AB The present invention provides methods of preventing, treating or ameliorating one or more symptoms of disorders in which modulation of a subject's immune system is beneficial utilizing a lymphoid tissue inducing agent and an immunomodulatory agent. In particular, the present invention provides methods of preventing, treating or ameliorating a proliferative disorder, an infectious disease, a cardiovascular disease, an autoimmune disorder, or an inflammatory disorder or one or more symptoms thereof comprising administering to a subject in need thereof one or more lymphoid tissue inducing agents and one or immunomodulatory agents. The present invention also provides compns. and articles of manuf. for use in preventing, treating or ameliorating one or more symptoms assocd. with disorders in which modulation of a subject's immune system is beneficial, including, but not limited to proliferative disorders, infectious diseases, cardiovascular diseases, autoimmune disorders and inflammatory disorders. The present invention further provides methods for screening and identifying lymphoid tissue inducing agents and/or immunomodulatory agents.

AB An app. and a method are provided for detecting an enzyme by measuring a change in deflection of a microcantilever having a substrate for the enzyme. The invention provides a method for detecting an enzyme, the method comprising: depositing a coating material on a first surface of at least one microcantilever; adding at least one substrate to the coating material, the substrate capable of interacting with the enzyme; exposing the microcantilever with the substrate to a sample; and measuring a deflection of the microcantilever, wherein the deflection indicates the presence of the enzyme in the sample. The substrate can be a biomaterial selected from the group consisting of a nucleic acid, a protein, a lipid, a hydrocarbon, and a polysaccharide. The invention is of use in proteomics, drug discovery, medical research, medical, veterinary, dental diagnostics, forensics, and military applications.

AB Recent clinical data shows that **arsenic** trioxide (As(2)O(3)) causes remission in patients with acute promyelocytic leukemia and multiple myeloma without severe side effects. Laboratory data suggest that As(2)O(3) induces apoptosis or cell differentiation of hematopoietic or solid tumor cells. To date, there has been no study on the effects of As(2)O(3) on glioma cells. In this study, we investigated the in vitro effect of As(2)O(3) on cell growth inhibition and cell death mechanisms in human glioma cells. As(2)O(3) significantly inhibited the proliferation of all six of the glioma cell lines (U373, U87, U251, GB1, A-172, and T98G) tested in this study in a dose-dependent manner. The IC(50) of As(2)O(3) for all of the tumor cell lines was <2 .mu.M. Previous studies have shown that this is a clinically safe concentration. Treatment with 2 .mu.M As(2)O(3) induced G(2)/M arrest in all of the glioma cell lines. Autophagy (programmed cell death type II), but not apoptosis (programmed cell death type I), was detected by electron microscopy in U-373-MG cells treated with 2 .mu.M As(2)O(3). Caspase inhibitors did not halt As(2)O(3)-induced cell death. Furthermore, combination of As(2)O(3) with bafilomycin A1 autophagy inhibitor enhanced the antitumor effect of As(2)O(3) through induction of apoptosis. These findings suggest that As(2)O(3) at a clinically safe concentration may be an effective chemotherapeutic agent for malignant gliomas.

AB Purpose: Among patients with multiply relapsed **neuroblastoma** refractory to conventional chemotherapy, oral topotecan has often been used for palliation. Although toxicity was generally thought to be mild, the efficacy of such an approach remains unproven. Methods: The authors retrospectively analyzed patients with multiply relapsed or refractory **neuroblastoma** who were treated with oral topotecan for palliation. Each course was generally 1 mg/m(2)/d in two divided doses, for 21 consecutive days, repeated after a 1-week rest in patients without symptoms of progressive disease. Disease status was assessed by radiographic studies, urine catecholamine levels, and multiple bone marrow aspirations and biopsies. Results: Twenty patients between the ages of 3 and 34 (median 13 years) received 1 (n = 7), 2 (n = 3), 3 (n = 4), 4 (n = 2), 6 (n = 2), and 12 courses (n = 2). Prior treatments included multiple cycles of high-dose alkylator-based chemotherapy (n = 20), high-dose intravenous topotecan (n = 8), myeloablative chemotherapy or radioimmunotherapy (n = 10), or experimental biologic agents (n = 16). Anti-**neuroblastoma** effects were seen in five patients lasting 6 to 12 months; two additional patients remained stable for 4 months. Thirteen patients had progressive disease (11 after one or two cycles). Toxicity included diarrhea (n = 12) requiring a dose adjustment in three patients and discontinuation of the drug in a fourth, and myelosuppression (n = 11) requiring transfusion and/or granulocyte-colony stimulating factor support. Conclusions: Oral topotecan therapy has antitumor activity in a small percentage of patients with relapsed or refractory **neuroblastoma**. Toxicities, including diarrhea and myelosuppression, may necessitate a dose adjustment in this patient population. Low-dose oral topotecan may have utility in the treatment of **neuroblastoma**.

AB Cancer occurs and it is life that runs off the rails. To restore the melody, the oncologist can use an array of pharmacological instruments which he needs to tune optimally to reach the maximal efficacy. Camptothecin derivatives, inhibitors of topoisomerase I, represent an essential family of the chemotherapeutic **arsenal**. Topotecan and irinotecan have been used in the clinic for a number of years, but other potent analogues are appearing and broaden the range of topoisomerase I poisons. In this review, we present the main molecular characteristics of the second generation of camptothecins (lurtotecan, exatecan, rubitecan, silatecan). The future is also evoked with camptothecin derivatives bearing a modified lactone ring, in particular the homocamptothecins and the drug diflomotecan, which shows promise as an anticancer. The camptothecin partition is disclosed here.
AB . . . tune optimally to reach the maximal efficacy. Camptothecin derivatives, inhibitors of topoisomerase I, represent an essential family of the chemotherapeutic **arsenal**. Topotecan and irinotecan have been used in the clinic for a number of years, but other potent analogues are appearing. . .

AB Previously, we showed that **arsenic** trioxide potently inhibited the growth of myeloma cells and head and neck cancer cells. Here, we demonstrate that **arsenic** trioxide inhibited the proliferation of all the renal cell carcinoma cell lines (ACHN, A498, Caki-2, Cos-7, and Renca) except only one cell line (Caki-1) with IC(50) of about 2.5-10 microM. **Arsenic** trioxide induced a G(1) or a G(2)-M phase arrest in these cells. When we examined the effects of this drug on A498 cells, **arsenic** trioxide (2.5 microM) decreased the levels of CDK2, CDK6, cyclin D1, cyclin E, and cyclin A proteins. Although p21 protein was not increased by **arsenic** trioxide, this drug markedly enhanced the binding of p21 with CDK2. In addition, the activities of CDK2- and CDK6-associated kinase were reduced in association with hypophosphorylation of Rb protein. **Arsenic** trioxide (10 microM) also induced apoptosis in A498 cells. Apoptotic process of A498 cells was associated with the changes of Bcl-(XL), caspase-9, caspase-3, and caspase-7 proteins as well as mitochondria transmembrane potential (Deltapsi(m)) loss. Taken together, these results demonstrate that **arsenic** trioxide inhibits the growth of renal cell carcinoma cells via cell cycle arrest or apoptosis.

AB The article is a comprehensive review of the occurrence of hormetic dose-response relationships induced by inorganic agents, including toxic agents, of significant environmental and public health interest (e.g., **arsenic**, cadmium, lead, mercury, selenium, and zinc). Hormetic responses occurred in a wide range of biological models (i.e., plants, invertebrate and vertebrate animals) for a large and diverse array of endpoints. Particular attention was given to providing an assessment of the quantitative features of the dose-response relationships and underlying mechanisms that could account for the biphasic nature of the hormetic response. These findings indicate that hormetic responses commonly occur in appropriately designed experiments and are highly generalizeable with respect to biological model responses. The hormetic dose response should be seen as a reliable feature of the dose response for inorganic agents and will have an important impact on the estimated effects of such agents on environmental and human receptors.

AB Fibroblast growth factor-2 (FGF-2) is involved as an autocrine growth factor in the autonomous proliferation of glioma cells. To develop a new strategy for treating patients with glioma, we studied the effect on human glioma cells of a 16-mer oligopeptide with conformational similarity to the putative receptor-binding domain of FGF-2. A synthesized oligonucleotide was assessed its receptor-binding activity by BIAcore instrument. Its biological effect on glioma cell lines was examined in vitro by MTT assay. The peptide suppressed the in vitro growth of human glioma cells U87MG, T98G and U251MG cells, but not of A431 cells whose growth is not dependent on FGF-2. Apoptotic bodies were noted after 24-h incubation in the presence of the peptide; Ac-YVAD-CHO, a caspase-3 inhibitor, suppressed apoptosis. Furthermore, we examined the modulation of the cytotoxic effect of anticancer drugs by the oligopeptide. The addition of this oligopeptide to the chemotherapeutic agents CDDP, ACNU

and VP16 had additive effects in vitro. These results suggest that the pathway of the FGF-2 autocrine loop through the FGF receptor plays an important role in the proliferation of glioma cells. New drugs targeting this loop may be highly effective in treating FGF-2-dependent tumors. Our results suggest that its addition to the therapeutic **arsenal** may lead to improved treatment regimens for patients with FGF-2-dependent tumors.

AB . . . targeting this loop may be highly effective in treating FGF-2-dependent tumors. Our results suggest that its addition to the therapeutic **arsenal** may lead to improved treatment regimens for patients with FGF-2-dependent tumors.

PRAI US 2001-288885P P 20010504
AB The present invention relates to protein-protein interactions of adipocytes. More specifically, the present invention relates to complexes of polypeptides, or polynucleotides encoding the polypeptides, interaction domains of the polypeptides, methods for screening drugs which modulate the interaction of proteins, and pharmaceutical compns. that are capable of modulating the protein-protein interactions. Thus, gene expression profiles of differentiated and undifferentiated human PAZ6 cells indicated that genes for the following proteins were overexpressed in the differentiated cells (adipocytes): protein TPT1 (tumor protein, translationally controlled, 1), leptin, complement component 1, thymosin .beta.4, fibulin 1C, osteonectin, .beta.2-microglobulin, proteasome

subunit p31, huntingtin-interacting protein 2, and two interferon-inducible proteins. In a modified yeast two-hybrid system, the protein interaction domains of these proteins were used as bait to identify proteins with which they interact. The DVL1, DVL2, and DVL3 (dishevelled 1, 2 and 3) proteins of the Wnt signaling pathway were all found to interact with the PSMD8 protein, i.e., proteasome subunit p31.

AB This USEPA action promulgates national emission stds. for hazardous air pollutants (NESHAP) for primary Cu smelting. Primary Cu smelters can potentially emit significant amts. of certain toxic metals listed as hazardous air pollutants (HAP) in the Clean Air Act (CAA) Section 112(b)(1). These metals include Sb, As, Be, Cd, Co, Pb, Mn, Ni, and Se. Exposure to these substances has been demonstrated to cause adverse health effects, including diseases of the lung, kidney, **central nervous system**, and **cancer**. This final rule establishes emissions limitations and work practice stds. for primary Cu smelters that are, or are part of, a major source of HAP emissions and which use batch Cu converters. These stds. reflect application of the max. achievable control technol. (MACT). When fully implemented, EPA ests. the rule will reduce annual nationwide HAP emissions from this source category by .apprx.23% or 22 Mg/yr.

AB Recent knowledge on apoptosis has made it possible to devise novel approaches, which exploit this process to treat cancer. In this review, we discuss in detail approaches to induce tumor cell apoptosis, their mechanism of action, stage of development, and possible drawbacks. Finally, the obstacles yet to be overcome and the perspectives for potential clinical use of apoptosis-triggering approaches in cancer therapy in the future are assessed.

AB OBJECTIVE: To review the role of all-trans retinoic acid (ATRA) and **arsenic** trioxide in central nervous system (CNS) relapses of acute promyelocytic leukemia (APL). CASE SUMMARY: A 69-year-old white man diagnosed with APL presented with bleeding diathesis. His molecular and

cytogenetic studies were positive for promyelocytic leukemia-retinoic acid receptoralpha (PML-RARalpha) and t(15;17) transformation. Complete molecular and cytogenetic remission was achieved with ATRA, daunorubicin, and cytarabine. Within 6 months, the patient was readmitted for investigation of severe global headaches and an ataxic gait. His peripheral blood and cerebral spinal fluid were positive for PML-RARalpha fusion protein. Intrathecal chemotherapy and radiation, as well as ATRA, were the main treatment modalities provided. Molecular and cytogenetic remission was again obtained. Three months later, a second relapse occurred in the CNS and the peripheral blood. DISCUSSION: APL is typically treated with anthacycline-based chemotherapy and ATRA. Approximately 85-95% of patients achieve complete remission (CR); however, the relapse rate has been reported to be about 30-40%. A thorough literature search (MEDLINE, EMBASE, CANCERLIT, 1966-January 2002) revealed only 54 cases of extramedullary disease, of which 35 involved the CNS. CONCLUSIONS: The introduction of ATRA has improved patient survival dramatically. APL relapse, in general, has been in part attributable to repetitive or prolonged exposure to ATRA and the possibility of additional chromosomal changes, making the disease more refractory to treat. Given the evidence, one could argue that, with repeated ATRA treatment, CR duration may be shortened. However, limited data are available to guide the appropriate management of APL relapsed to the CNS with either ATRA, chemotherapy, or **arsenic** trioxide. In our opinion, treatment using **arsenic** trioxide is an unconventional option worthy of exploring.

AB **Arsenic** trioxide (As(2)O(3)) at low concentrations (1-10 microM) is effective in the treatment of acute promyelocytic leukemia (APL) and

lymphoma and is in clinical trials for treatment of solid tumors. Paclitaxel, an antimicrotubule agent, is highly efficacious in the treatment of adult tumors and is in clinical evaluation in childhood tumors. This study is the first to investigate the combination of **arsenic** and paclitaxel in the range of clinically achievable concentrations. We found that the simultaneous combination was antagonistic on proliferation of the **neuroblastoma** SK-N-SH cell line by using the combination index (CI) method. Moreover, a 40+/-5% decrease in paclitaxel-induced apoptosis in cells co-treated with As(2)O(3) confirmed the antagonism. The mechanism of antagonism was studied at the cellular level with 200 nM paclitaxel, twice the IC(50) value, and with 1 microM As(2)O(3) which administered singly did not affect cell survival or the microtubule network. As(2)O(3) antagonized the effects of paclitaxel on tubulin and microtubules. Paclitaxel-induced mitotic block was decreased by 20+/-2% and bundles induced by 200 nM paclitaxel were less condensed in the presence of 1 microM As(2)O(3). As(2)O(3) (10-200 microM) induced a concentration-dependent inhibition of tubulin polymerization in vitro which was maintained in presence of paclitaxel. Spectrophotometric and spectrofluorometric measurements indicated an interaction of As(2)O(3) with tubulin SH groups, without modification of the stoichiometry of paclitaxel binding to tubulin. Moreover, 4 microM As(2)O(3) inhibited the release of cytochrome c from isolated mitochondria by 78+/-10%. Our results show that As(2)O(3) and paclitaxel act antagonistically on mitochondria and microtubules and illustrate the need for careful evaluation of drug combinations.

TI Involvement of microtubules and mitochondria in the antagonism of **arsenic** trioxide on paclitaxel-induced apoptosis.

AB Occupational agents were evaluated for the risk of **brain**-nervous system **cancer** in a cohort of 413,877 Finnish women with blue-collar occupations in 1970. Observed and expected numbers of incident cases and the intensities of exposure to 25 agents were generated for 183 job titles from 1971 to 1995. Poisson regression models linked incidence and exposure data. Increased risks were found for medium/high intensities of iron (standardized incidence ratio [SIR], 2.15; 95% confidence interval [CI], 0.96 to 4.80), oil mist (1.95; 0.97 to 3.90), any chromium compounds (1.51; 0.85 to 2.67), electromagnetic fields (1.37; 0.98 to 2.10), aliphatic and alicyclic hydrocarbon compounds (1.34; 0.80 to 2.27), lead (1.27; 0.81 to 2.01), cadmium (1.26; 0.72 to 2.22), and aromatic hydrocarbon compounds (1.20; 0.71 to 2.03). Strengths of the study include fair number of cases, virtually complete case coverage, and a high-quality job exposure matrix. Ecological design and cross-sectional job assessment introduced exposure misclassification and tended to drive risk estimates toward unity.

AB Neurons in vivo are exposed to a variety of different growth factors and cytokines. A principal signalling pathway for ciliary neurotrophic factor (CNTF)-like cytokines is the Janus kinase (Jak)/signal transducer and activator of transcription (STAT) system of kinases and transcription factors. In the human cell line (SH-SY5Y), STAT1 and STAT3 activation by CNTF-like cytokines showed tyrosine phosphorylation peaking at 0.5 h and inactivating within 2 h. Tyrosine phosphorylation of the receptor-associated tyrosine kinases Jak1 and Jak2 showed a similar time course of activation and inactivation in response to CNTF. The STAT1 response to the non-CNTF-like cytokine, interferon-gamma (IFN-gamma) did not inactivate. Inactivation to CNTF was not due to a decrease in CNTF receptor subunit gp130 or in levels of Jak1 or Jak2. STAT inactivation was inhibited by the protein kinase blocker H7 and a tyrosine phosphatase blocker, but not by inhibitors of protein kinase C, mitogen-activated protein kinase (MAPK) kinase, mTOR-P70/S6 kinase or phosphatidyl inositol-3-kinase (PI-3 kinase). Surprisingly, CNTF caused only a minor increase in levels of suppressors of cytokine signalling, SOCS-1 and SOCS-3. CNTF pretreatment desensitized the cells to the CNTF-like cytokines, leukemia inhibitory factor and oncostatin-M but not to IFN-gamma. These results reveal a complex level of regulation of shared signalling pathways for cytokines that is dependent on both the type of cell and cytokine.

AB In most cervical cancer cells, p53 and Rb are disrupted by human papillomaviruses (HPVs) E6 and E7, respectively. Restoration of p53 or Rb function by blocking E6/p53 or E7/Rb pathway might be a potential therapeutic purpose for these cancer cells. Treatment with sodium **arsenite** (SA) resulted in significant repression of E6 and E7 mRNA levels in SiHa cells. After E6 and E7 repression, p53 was dramatically induced and accumulated in cellular nuclei and Rb was also induced. Two p53-responsive genes, p21(waf1/cip1) and mdm2, were induced after SA treatment. Furthermore, SA also reduced the expressions of Cdc25A and cyclin B, blocked cell cycle progression at G2/M phase, and induced apoptosis in SiHa cells. SA-induced apoptosis was greatly reduced by expression of a dominant-negative mutated p53. In this study, we have first demonstrated that SA did repress E6 and E7 oncogenes, restore the p53 tumor suppressor pathway and induce apoptosis in SiHa cells. Therefore, it would be a potential strategy to promote SA as therapeutic purpose for HPV-positive cancer cells.

AB Amyloid .beta.(1-42), a major component of amyloid plaques, binds with exceptionally high affinity to the .alpha.7 nicotinic acetylcholine receptor and accumulates intracellularly in neurons of Alzheimer's disease brains. In this study, we investigated the possibility that this binding plays a key role in facilitating intraneuronal accumulation of amyloid .beta.(1-42). Consecutive section immunohistochemistry and digital imaging were used to reveal the spatial relationship between amyloid .beta.(1-42) and the .alpha.7 receptor in affected neurons of Alzheimer's disease brains. Results showed that neurons containing substantial intracellular accumulations of amyloid .beta.(1-42) invariably express relatively high levels of the .alpha.7 receptor. Furthermore, this receptor is highly co-localized with amyloid .beta.(1-42) within neurons of Alzheimer's disease brains. To experimentally test the possibility that the binding interaction between exogenous amyloid .beta.(1-42) and the .alpha.7 receptor facilitates internalization and intracellular accumulation of amyloid .beta.(1-42) in Alzheimer's disease brains, we studied the fate of exogenous amyloid .beta.(1-42) and its interaction with the .alpha.7 receptor in vitro using cultured, transfected **neuroblastoma** cells that express elevated levels of this receptor. Transfected cells exhibited rapid binding, internalization and accumulation of exogenous amyloid .beta.(1-42), but not amyloid .beta.(1-40). Furthermore, the rate and extent of amyloid .beta.(1-42) internalization was related directly to the .alpha.7 receptor protein level, since (1) the rate of amyloid .beta.(1-42) accumulation was much lower in untransfected cells that express much lower levels of this receptor and (2) internalization was effectively blocked by .alpha.-bungarotoxin, an .alpha.7 receptor antagonist. As in neurons of Alzheimer's disease brains, the .alpha.7 receptor in transfected cells was precisely co-localized with amyloid .beta.(1-42) in prominent intracellular aggregates. Internalization of

amyloid .beta.(1-42) in transfected cells was blocked by phenylarsine oxide, an inhibitor of endocytosis. We suggest that the intraneuronal accumulation of amyloid .beta.(1-42) in Alzheimer's disease brains occurs predominantly in neurons that express the .alpha.7 receptor. In addition, internalization of amyloid .beta.(1-42) may be facilitated by the high-affinity binding of amyloid .beta.(1-42) to the .alpha.7 receptor on neuronal cell surfaces, followed by endocytosis of the resulting complex. This provides a plausible explanation for the selective vulnerability of neurons expressing the .alpha.7 receptor in Alzheimer's disease brains and for the fact that amyloid .beta.(1-42) is the dominant amyloid .beta. peptide species in intracellular accumulations and amyloid plaques.

AB . . . we studied the fate of exogenous amyloid .beta.(1-42) and its interaction with the .alpha.7 receptor in vitro using cultured, transfected **neuroblastoma** cells that express elevated levels of this receptor. Transfected cells exhibited rapid binding, internalization and accumulation of exogenous amyloid .beta.(1-42),. . .

AB Imexon is an aziridine-contg. iminopyrrolidone with selective growth-inhibitory potency for multiple myeloma. Our previous research indicates that imexon induces mitochondrial alterations, oxidative stress, and apoptosis. This drug represents an interesting model drug with a nonmyelosuppressive profile to study the basic mechanisms leading to antitumor activity and resistance. The major purpose of this study was to characterize an imexon-resistant RPMI8226/I cell line that was developed from RPMI8226 cells by continuous exposure to imexon. No significant differences were obsd. in the sensitivity to several cytotoxic drugs, including mitoxantrone, mitomycin C, melphalan, methotrexate, cytarabine, cisplatin, vincristine, and paclitaxel, in the imexon-resistant cells. However, RPMI8226/I cells were cross-resistant to **arsenic** trioxide, doxorubicin, fluorouracil, etoposide, irinotecan, and esp. IFN-.alpha.. The data from DNA microarray and Western blot analyses indicated that the levels of antiapoptotic proteins Bcl-2 and thioredoxin-2, which reside mainly in the mitochondria, are increased in RPMI8226/I cells. In addn., increased levels of lung resistance protein were detected in imexon-resistant cells. Expression of P-glycoprotein was not detected in RPMI8226/I cells. No loss of mitochondrial membrane potential or increase in the levels of reactive oxygen species was obsd. in RPMI8226/I cells after exposure to imexon; however, the levels of glutathione are increased in the RPMI8226/I cells. TEM revealed significant changes in the mitochondrial morphol. of RPMI8226/I cells, whereas no ultrastructural changes were obsd. in other cellular compartments. Imexon-resistant RPMI8226/I myeloma cells appear to have a unique mechanism of resistance that is assocd. with morphol. alterations of mitochondria, increased protection against oxidative stress, elevated levels of glutathione, and enhanced expression of antiapoptotic mitochondrial proteins.

AB The growth of solid tumors and metastases beyond a limited size of 1-2 mm(3) in diameter depends on angiogenesis. This dynamic process is tightly controlled by a large number of proangiogenic and antiangiogenic factors, their receptors and signal transduction pathways respectively which are representing new targets for an antiangiogenic therapy. Many of these factors are involved with an intrinsic or associated tyrosine kinase activity. The pharmacodynamic targeting of tumor angiogenesis may be divided into seven major categories: 1. Antagonists of angiogenic growth factors 2. Inhibitors of endothelial cell signal transduction 3. Inhibitors of endothelial cell proliferation and migration 4. Inhibitors of cell adhesion molecules 5. Vascular thrombosis inducing agents 6. Non-selective angiogenesis inhibitors 6.1 Matrix metalloproteinase inhibitors 6.2 Inhibitors of cofactors 7. Anti-angiogenic agents with different mechanisms of action Angiogenesis inhibitors were investigated in clinical trials for the therapy of solid tumors, like lung (SCLC, NSCLC), breast, colon, gastric tumors, **glioblastoma**, melanoma, in addition lymphomas and multiple myeloma, where effective conventional therapies and regimes do not exist so far. Finally the antiangiogenic therapy is compared with conventional chemotherapy. The pharmacological profile of angiogenesis inhibition differs basically from established chemotherapy: As a result of in the unique therapeutic target at the tumor endothelial cells, the drug resistance may be less a problem. Other differerences are the moderate spectrum of side effects, the longterm maintenance therapy and the cytostatic mechanism of action. Also combination of antiangiogenic agents with conventional cytotoxic drugs enhances the effect of the latter. At the end of 2001 approx. 50 angiogenesis inhibitors were investigated in clinical studies I-III, in the next three years the first antiangiogenic drug for the treatment of neoplasms will be on approval.

AB Toxicity results from submitochondrial particle (SMP) bioassays were compared to results from multiple human-cell-based assays to evaluate the SMP tests' ability to indicate cellular toxicity. Correlation analyses between cell-based and SMP responses were conducted on a series of diverse chems. of human toxicol. interest chosen in the Multicentre Evaluation of In vitro Cytotoxicity (MEIC) study and suggest a high degree of ordering. The r2 correlation coeff. obtained when comparing the log-transformed SMP results to the av. cellular response for all compds. was 0.75 (n=42). When specific mitochondrial inhibitors (to which SMP arc extremely sensitive) and toxic metals (which SMP modeled poorly) were removed, the correlation improved to 0.91 (n=34). When the SMP assay of each individual cell-based assay was compared to the av. toxic response of all the cell-based assays for these 34 compds., the SMP r2 was greater than the median r2 of the cell-based assays, indicating its ability to predict cell-based toxic responses with a high degree of accuracy. Comparisons of the SMP data to the human toxicity data are similar to the cell line assays, where removal of the specific mitochondrial toxicants and metals greatly improves the relationship.

AB Recent clinical studies have demonstrated that As2O3 is an effective drug in the treatment of acute promyelocytic leukemia (APL) by inducing apoptosis and inhibiting the proliferation of leukemia cells both in vitro and in vivo. As a novel anticancer agent for the treatment of solid cancer, As2O3 is promising, but no experimental investigations of its efficacy on **glioblastoma** have been conducted at concentrations that may be achieved clinically. In addition, the cell proliferation and cell cycle regulating mechanism of As2O3 has not yet to be clarified,

especially in solid cancers. We investigated the effect of As2O3 on proliferation and cell cycle regulation with change in cyclins in two human **glioblastoma** cell lines differing in p53 status (U87MG-wt; T98G-mutated). Sensitivity to As2O3 varied depending on the dose with the IC50 of the U87MG and T98G cells being 1.78 and 3.55 microM, respectively. Analysis by laser scanning cytometry (LSC) indicated that As2O3 inhibited the proliferation of the two cell lines via cell cycle arrest both at the G1 and G2 phases. To address the mechanism of the antiproliferative effect of As2O3, we examined its effect on cell cycle-related proteins by means of LSC, confocal microscopy and Western blot analysis. As2O3 induced an increase in p53 level and a decrease in level of cyclin B1 combined with cell arrest at G2/M in both cell lines. Cell arrest in G1, however, was associated with a decline in cyclin D1 expression only in the wt U87MG cells. As2O3 also induced apoptosis of U87MG cells as evidenced by the presence of cells with fractional DNA content (cell populations). The present evidence that As2O3 at relatively low concentration effectively inhibited proliferation of U87MG and T98G cells in vitro, suggests that the drug may be considered for in vivo testing on animal models and possibly clinical trials on glioma patients.

TI Effect of As2O3 on cell cycle progression and cyclins D1 and B1 expression in two **glioblastoma** cell lines differing in p53 status.

AB It is well-known that p38 mitogen-activated protein kinase (p38MAPK) participates in cellular responses to mitogenic stimuli, environmental and genotoxic stresses, and apoptotic agents. Although there are several reports on p38MAPK in relation to cell growth and apoptosis, the exact mechanism of p38MAPK-mediated cell growth regulation remains obscure. Here, we examined possible roles of p38MAPK in the sodium **arsenite** -induced cell growth inhibition in NIH3T3 cells. Sodium **arsenite** induced transient cell growth delay with marked activation of p38MAPK. In addition, **arsenite** induced CDK inhibitor p21(CIP1/WAF1) and enhanced its binding to the CDK2, which resulted in inhibition of CDK2 activity. The levels of cyclin D1 expression and the CDK4 kinase activity were also significantly reduced. pRB was hypophosphorylated by sodium **arsenite**. SB203580, a specific inhibitor of p38MAPK, blocked **arsenite**-induced growth inhibition as well as the **arsenite** -induced p21(CIP1/WAF1) expression. Expression of dominant negative p38MAPK also blocked **arsenite**-induced p21(CIP1/WAF1) expression. Inhibited-CDK2 activity was also completely reversed by SB203580 or expression of dominant negative p38MAPK, while the decreased-cyclin D1 protein by the compound was not restored. These data demonstrate a possible link between the activation of p38MAPK and induction of p21(CIP1/WAF1), suggesting that the activation of p38MAPK is, at least in part, related to the cell growth inhibition by sodium **arsenite**.

AB The invention provides a composite for the treatment of a variety of medical conditions, the composite comprising an oxidized glutathione-based compd., which has a disulfide bond, and a metal material, in particular where the metal is either platinum or palladium. The oxidized glutathione-based compd. and metal material can be present in a ratio of 3000:1 and preferably 1000:1. The oxidized glutathione-based compd. can be oxidized glutathione itself or salts or derivs thereof. A feature of the invention is that the composite has a more stabilized disulfide bond than the oxidized glutathione-based compd. itself. Methods for prepg. the composite are provided, such methods being beneficial in that the composite is provided in high yields and at high purity. Methods for treating various medical conditions with the composites of the present invention are also disclosed.

AB In vitro studies that showed RA could cause growth arrest and differentiation of myelogenous leukemia and **neuroblastoma** led to clinical trials of retinoids in APL and **neuroblastoma** that increased survival for both of those diseases. In the case of APL, ATRA

has been the drug of choice, and preclinical and clinical data support direct combinations of ATRA with cytotoxic chemotherapy. For **neuroblastoma**, a phase I study defined a dose of 13-cis-RA, which was tolerable in patients after myeloablative therapy, and a phase III trial that showed postconsolidation therapy with 13-cis-RA improved EFS for patients with high-risk **neuroblastoma**. Preclinical studies in **neuroblastoma** indicate that ATRA or 13-cis-RA can antagonize cytotoxic chemotherapy and radiation, so use of 13-cis-RA in **neuroblastoma** is limited to maintenance after completion of cytotoxic chemotherapy and radiation. A limitation on the antitumor benefit of ATRA in APL is the marked decrease in drug levels that occurs during therapy as a result of induction of drug metabolism, resulting in a shorter drug half-life and decreased plasma levels. Although early studies sought to overcome the pharmacologic limitations of ATRA therapy in APL, the demonstration that ATO is active against APL in RA-refractory patients(178, 230, 246) has led to a focus on studies employing ATO. Use of 13-cis-RA in **neuroblastoma** has avoided the decreased plasma levels seen with ATRA. It is likely that recurrent disease seen during or after 13-cis-RA therapy in **neuroblastoma** is due to tumor cell resistance to retinoid-mediated differentiation induction. Studies in **neuroblastoma** cell lines resistant to 13-cis-RA and ATRA have shown that they can be sensitive, and in some cases collaterally hypersensitive, to the cytotoxic retinoid fenretinide. Fenretinide induces tumor cell cytotoxicity rather than differentiation, acts independently from RA receptors, and in initial phase I trials has been well tolerated. Clinical trials of fenretinide, alone and in combination with ceramide modulators, are in development.

AB In vitro studies that showed RA could cause growth arrest and differentiation of myelogenous leukemia and **neuroblastoma** led to clinical trials of retinoids in APL and **neuroblastoma** that increased survival for both of those diseases. In the case of APL, ATRA has been the drug of choice, and preclinical and clinical data support direct combinations of ATRA with cytotoxic chemotherapy. AB A review, describing the use of **arsenic** compds. as anticancer agents in clin. trials and in vitro. As2O3 treatment of newly diagnosed and relapsed patients with acute promyelocytic leukemia (APL) has been found to result in complete remission (CR) rates of 85-93% when given by i.v. infusion for 2-3 h at 10 mg/day dild. in 5% glucose/saline soln. Patients exhibited a response after 28-42 days. CR rates after administration of Composite Indigo Naturalis tablets contg. **arsenic** sulfide and of pure tetraarsenic tetrasulfide reached 98% and 84.9%, resp. At high concns. (1-2 .mu.M), As2O3 induced apoptosis in various types of cancer cells in vitro, while at lower concns. (0.1-0.5 .mu.M), it triggered cell differentiation. This As2O3-induced apoptosis has been obsd. in many cancer cell lines, including esophageal carcinoma, gastric cancer, **neuroblastoma**, lymphoid malignancies, and

multiple myeloma. Its effectiveness was confirmed in the clin. treatment of multiple myeloma. **Arsenic** compds. are effective agents in the treatment of APL, and their activity against other types of cancer requires further investigation.

AB A method of delivering an active agent to a target tissue, particularly neoplastic tissue, vascular anomaly or tumor tissue, in a vertebrate subject. The method includes the steps of exposing the target tissue to ionizing radiation; and administering a delivery vehicle to the vertebrate subject before, after, during, or combinations thereof, exposing the

target tissue to the ionizing radiation. The delivery vehicle includes the active agent and delivers the agent to the target tissue. Representative delivery vehicles include platelets; leukocytes; proteins or peptides which bind activated platelets; antibodies which bind activated platelets; microspheres coated with proteins or peptides which bind activated platelets; liposomes conjugated to proteins or peptides, platelets, or leukocytes which bind activated platelets, or antibodies which bind activated platelets; and combinations thereof.

AB Tau is a microtubule-associated protein (MAP) that is functionally modulated by phosphorylation and that is hyperphosphorylated in several neurodegenerative diseases. Because phosphorylation regulates both normal and pathological tau functioning, it is of interest to identify the signaling pathways and enzymes capable of modulating tau phosphorylation in vivo. Previously, it was demonstrated that in SH-SY5Y human **neuroblastoma** cells and rat primary cortical cultures tau is phosphorylated at Ser262/356, within its microtubule-binding domain, by a staurosporine-sensitive protein kinase in response to the vicinal thiol-directed agent phenylarsine oxide. The current study demonstrates the presence of a 100-kDa protein kinase activity in SH-SY5Y cells that associates with microtubules, phosphorylates tau at Ser262/356, is activated by phenylarsine oxide, and is inhibited by the protein kinase inhibitor staurosporine. Isolation of individual protein bands from a polyacrylamide gel revealed two closely spaced proteins containing Ser262/356-directed protein kinase activity. Mass spectrometry analysis indicated that these protein bands correspond to the 100-kDa microtubule/MAP-affinity regulating kinase (MARK), which has been shown previously to phosphorylate tau within its microtubule-binding domain. Immunoblot analysis of the protein kinase bands confirmed this finding, providing the first demonstration that activation of endogenous MARK results in increased tau phosphorylation within its microtubule-binding domain in situ.
AB . . . the signaling pathways and enzymes capable of modulating tau phosphorylation in vivo. Previously, it was demonstrated that in SH-SY5Y human **neuroblastoma** cells and rat primary cortical cultures tau is phosphorylated at Ser262/356, within its microtubule-binding domain, by a staurosporine-sensitive protein kinase. . .

AB A review with 47 refs. A novel therapeutic potential for acute promyelocytic leukemia using **arsenic** trioxide (As2O3) has been reported. Recent in vitro studies demonstrated that As2O3 effectively inhibits the growth of some cell lines derived from patients with malignant lymphoma, chronic lymphocytic leukemia and multiple myeloma. Adult T-cell leukemia (ATL) is an aggressive neoplasm of mature T-cell origin caused by human T-cell leukemia virus type-I (HTLV-I) the prognosis of which still remains very poor. A possible role of As2O3 for the treatment of ATL is demonstrated from evidence that As2O3 significantly inhibits the growth of HTLV-I infected T-cell lines and induces apoptosis in fresh ATL cells at clin. achievable concn. of the agent. The growth inhibition of As2O3 treated HTLV-I infected T-cell lines was induced by both apoptosis and G1 phase accumulation. Cleaved bcl-2 protein and an enhanced expression of bak protein in the cells were coincidentally obsd. during As2O3 treatment. A broad spectrum caspase inhibitor, z-Val-Ala-DL-Asp-fluoromethylketone inhibited the apoptosis induced by As2O3. Increased expression of p53, Cip1/p21 and Kip1/p27, and dephosphorylation of **retinoblastoma** protein (pRb) were detected in the As2O3 treated cells. In conclusion, As2O3 might become a new therapeutic tool in the treatment of ATL as As2O3 induces apoptosis by destruction of the bcl-2 protein and enhancement of the bak protein prodn. to activate caspases, and also induces G1 phase accumulation by enhancement of p53, Cip1/p21, Kip1/p27 and dephosphorylation of pRb.

AB Most chemical carcinogenic agents are industrial. About 4% of all cancers have an occupational origin, but the percentage is higher in exposed populations. Evidence of carcinogenicity is provided by epidemiological studies, animal experiments and other biological sources like experimental mutagenesis. The IARC (International Agency for Research on Cancer) classification and the European Union classification of carcinogenic agents for humans are useful for prevention and regulation. Some cancers are classified as occupational diseases but only a few persons receive compensation given the difficulties of aetiologic diagnosis and the frequent absence of declaration.

AB Background. Lead is only weakly mutagenic, but in vitro it inhibits DNA repair and acts synergistically with other mutagens. Lead acetate administered orally, cutaneously, or i.p. causes kidney **cancer**, **brain cancer** (gliomas), and lung **cancer** in rodents, and acts synergistically with other carcinogens. Most cytogenetic studies of exposed workers have shown increases in chromosome aberrations or sister chromatid exchange, including some studies with pos.-exposure response trends. There are 8 studies of cancer mortality or incidence among highly exposed workers; most are cohort studies of lead smelter or battery workers exposed decades ago. Methods. The authors reviewed the epidemol. studies with regard to cancer. Results. These studies provide some evidence of increased risk of lung cancer (RR=1.30, 1.15-1.46, 675 obsd. deaths) and stomach cancer (combined RR=1.34, 1.14-1.57, 181 obsd.). However, the lung cancer findings are not consistent across studies, and confounding by **arsenic** may affect the study with the highest lung cancer RR. Exclusion of that study yields a combined lung cancer RR of 1.14 (1.04-1.73). There is little evidence of increased risk of kidney cancer (combined RR=1.01, 0.72-1.42, 40 obsd.) or **brain cancer** (combined RR=1.06, 0.81-1.40, 69 obsd.). However, 2 studies show a 2-fold increase in kidney cancer, and one study shows a significant excess of gliomas. IARC classified lead as a possible human carcinogen based on sufficient animal data and

insufficient human data in 1987. Six of the 8 studies cited above have been published since 1987. Conclusion. Overall, there is only weak evidence assocg. lead with cancer; the most likely candidates are lung cancer, stomach cancer, and gliomas.

AB Controlled delivery of chemotherapeutic agents by biodegradable polymers is a new strategy that has been added to the **arsenal** available for the treatment of malignant neoplasms. This approach is particularly suitable for the management of **brain tumours** because of the constraints imposed by the blood brain barrier (BBB). The use of polymers for local drug delivery minimises systemic toxicity, while achieving prolonged elevation of intratumoural drug concentrations that results in improved efficacy. In addition, this strategy broadens the spectrum of drugs available for the treatment of **neoplasms** in the **central nervous system** to include agents whose efficacy is significantly limited by systemic toxicity or inability to penetrate the BBB. In this review, we discuss the rationale and background for the use of this novel approach. We also summarise the clinical trials and laboratory investigations leading to the development of local delivery of anti-neoplastic agents from biodegradable polymers for the treatment of malignant gliomas.

AB Studies from China and New York have recently documented that daily intravenous doses of A<SC>s</SC>[Subscript 2]O[Subscript 3] are highly effective for remission induction in patients with acute promyelocytic leukemia. Preclinical studies have shown that this agent also has activity against several solid tumor cell lines. To test whether this agent could be clinically useful in a more convenient dosing schedule, we initiated a phase 1 study to determine the safety of A<SC>s</SC>[Subscript 2]O[Subscript 3] administered as a daily IV infusion over 1--2 hours for 5 days every 4 weeks in patients with advanced solid tumors. To date, 13 patients have been enrolled with the following tumor types: **Neuroblastoma** (3), renal cell (2), non-small cell lung (1), thyroid (1), colon (1), stomach (1), ovary (1), esophagus (1), Ewing's sarcoma (1) and Merkel cell (1). The initial dose was 0.15 mg/kg, which has been escalated in successive patient cohorts by 0.05 mg/kg. Blood and urine samples have been analyzed by injection coupled plasma mass spectroscopy. Ten patients are evaluable for toxicity and 6 for response after receiving a median of 2 cycles (range, 1--3). One patient with **neuroblastoma** has had a minor response. Adverse reactions have included fatigue (6), hyperglycemia (7), headache (2), and prolong QTc (2). Patients are currently being entered at a dose of 0.25 mg/kg. Up to this dose, A<SC>s</SC>[Subscript 2]O[Subscript 3] has been well-tolerated, and no patients have required dose attenuation. Since severe reactions have been reported after abrupt dose-escalations, this study will determine the safety and upper limits of tolerability of A<SC>s</SC>[Subscript 2]O[Subscript 3] using a dosing regimen suitable for out-patient therapy of patients with advanced cancer.

My Case

AB WO 9918798 A UPAB: 20021105

NOVELTY - Solid tumors or metastatic neoplastic disease or hematopoietic disorders are treated by administration of one or more **arsenic** compounds (I).

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

(a) treatment of neoplastic diseases in humans comprising administration of (I) or its salt in combination with at least one other therapeutic agent;

(b) an oral pharmaceutical composition useful for treating neoplastic diseases in a human comprising (I) or its salt and a carrier, diluent or excipient; and

(c) a sterile unit dosage form adapted for parenteral administration comprising a non-lethal amount of **arsenic** trioxide in an aqueous carrier, the dosage form being contained in a sealed glass container.

ACTIVITY - Anticancer.

MECHANISM OF ACTION - Phosphorous analogue able to interfere with signal transduction in apoptosis; inhibitor of angiogenesis.

USE - The method is particularly useful for treatment of tumors of the epithelial tissue, preferably epithelial glands, epithelial ducts, liver, biliary tract, gastrointestinal tract, respiratory tract or urogenital tract, lymphoid tissue, connective tissue, bone or **central nervous system**, metastatic **neoplastic** diseases of the epithelial tissue, lymphoid tissue, connective tissue, bone or **central nervous system**. The **tumor** is preferably a squamous cell carcinoma of the esophagus, adenocarcinoma of esophagus, colorectal carcinoma, gastric carcinoma, Hodgkins lymphoma, non-Hodgkin's lymphoma, follicular lymphoma, diffuse lymphoma, lymphoblastic lymphoma, large cell lymphoma, small lymphocytic lymphoma, **neuroblastoma**, **retinoblastoma**, **glioblastoma** or **oligodendroglioma** (all claimed).

The compounds are also useful for the treatment of metastatic neoplastic diseases, e.g. primary and metastatic **tumors** of the **central nervous system**, refractory primary and metastatic **tumors** of the **central nervous system**, breast, lung, bladder and prostate **cancer** and refractory breast, lung, bladder and prostate cancer.

DESCRIPTION OF DRAWING(S) - The figure is a dose response curve for leukemic cell lines CCRF-CEM, HL-60(TB), K-562, MOLT-4, RPMI-8226 and SR after continuous exposure to 10-5 to 10-9 mu g/ml **arsenic** trioxide for 2 days.

AB We have recently shown a close correlation between expression of the Multidrug Resistance-associated Protein (MRP) gene and the MYCN oncogene and provided evidence that high MRP expression is a powerful independent predictor of poor outcome in **neuroblastoma** (Norris et al., New Engl. J. Med., 334, 231-238, 1996). The effect of MYCN down-regulation on MRP expression and response to cytotoxic drugs was investigated in NBL-S **neuroblastoma** cells transfected with MYCN antisense RNA constructs. Concomitant with MYCN down-regulation, the level of MRP expression was decreased in the NBAS-4 and NBAS-5 antisense transfectants. These cells demonstrated significantly increased sensitivity to the high affinity MRP substrates vincristine, doxorubicin, sodium **arsenate** and potassium antimony tartrate, but not to the poor MRP substrates, taxol or cisplatin. Similarly, transfection of full-length MYCN cDNA into SH-EP **neuroblastoma** cells resulted in increased MRP expression and significantly increased resistance specifically to MRP substrates. The results provide evidence for the MYCN oncogene influencing cytotoxic drug response via regulation of MRP gene expression. Our data also provide a link between the malignant and chemoresistant phenotypes of this childhood malignancy.
TI Altered expression of the MYCN oncogene modulates MRP gene expression and response to cytotoxic drugs in **neuroblastoma** cells.

AB The effect of phosphoinositide depletion on focal adhesion kinase (FAK) signaling was investigated in two neuronal cell lines. Treatment of either SH-SY5Y **neuroblastoma** cells or PC12 cells with wortmannin, at a concentration that inhibits phosphatidylinositol 4-kinase activity, led to a selective depletion of phosphatidylinositol 4-phosphate without significantly altering phosphatidylinositol 4,5-bisphosphate (PIP2) content. An enhanced tyrosine phosphorylation of FAK elicited by agonist occupancy of phospholipase C-coupled receptors (muscarinic cholinergic in SH-SY5Y **neuroblastoma** or bradykinin in PC12 cells) was blocked completely by wortmannin. Under the above conditions, phosphoinositide resynthesis was prevented, and as a consequence, receptor stimulation led to a marked depletion of PIP2. In contrast, the increased tyrosine phosphorylation of FAK elicited by agents that do not activate phospholipase C (phenylarsine oxide, lysophosphatidic acid, or phorbol ester) persisted in the presence of wortmannin. However, the ability of these agents to elicit an increase in FAK phosphorylation was also prevented if PIP2 was depleted by activation of a phospholipase C-coupled receptor in the presence of wortmannin. The results suggest that agonist-sensitive pools of PIP2 must be maintained for FAK signaling to occur in response to a mechanistically diverse range of stimuli.

AB Tau is a microtubule-stabilizing protein that is functionally modulated by alterations in its phosphorylation state. Because phosphorylation regulates both normal and pathological tau functioning, it is of importance to identify the signaling pathways that regulate tau phosphorylation in vivo. The present study examined changes in tau phosphorylation and function in response to modulation of cellular thiol content. Treatment of cells with phenylarsine oxide, which reacts with vicinal thiols, selectively increased tau phosphorylation within its microtubule-binding domain, at the non-Ser/Thr-Pro sites Ser262/356, while decreasing tau phosphorylation at Ser/ Thr-Pro sites outside this region. This increase in tau phosphorylation correlated with a decrease in the amount of tau associated with the cytoskeleton and decreased microtubule stability. Phenylarsine oxide-induced tau phosphorylation was inhibited by oxidants and by the protein kinase inhibitor staurosporine. Although staurosporine completely eliminated the increase in tau phosphorylation at Ser262/356, as detected by immunostaining with 12E8, it had a comparatively minor effect on the changes in tau localization induced by phenylarsine oxide. The results suggest that regulation of cellular thiols is important for modulating tau phosphorylation and function in situ. Additionally, although phosphorylation of Ser262/356 decreases tau's interaction with the cytoskeleton, phosphorylation of these residues alone is not sufficient for the phenylarsine oxide-induced changes in tau localization.

AB **Arsenic** trioxide (As2O3) can induce clin. remission in patients with acute promyelocytic leukemia via induction of differentiation and programmed cell death (apoptosis). We investigated the effects of As2O3 on a panel of malignant lymphocytes to det. whether growth-inhibitory and apoptotic effects of As2O3 can be obsd. in these cells at clin. achievable concns. Eight malignant lymphocytic cell lines and primary cultures of lymphocytic leukemia and lymphoma cells were treated with As2O3, with or without dithiothreitol (DTT) or buthionine sulfoximine (BSO) (an inhibitor of glutathione synthesis). Apoptosis was assessed by cell morphol., flow cytometry, annexin V protein level, and terminal deoxynucleotidyl transferase labeling of DNA fragments. Cellular proliferation was detd. by 5-bromo-2'-deoxyuridine incorporation into DNA and flow cytometry and by use of a mitotic arrest assay. Mitochondrial transmembrane potential (.DELTA..psi.m) was measured by means of rhodamine 123 staining and flow cytometry. Protein expression was assessed by western blot anal. or immunofluorescence. Therapeutic concns. of As2O3 (1-2 .mu.M) had dual effects on malignant lymphocytes: 1) inhibition of growth through ATP (ATP) depletion and prolongation of cell cycle time and 2) induction of apoptosis. As2O3-induced apoptosis was preceded by .DELTA..psi.m collapse. DTT antagonized and BSO enhanced As2O3-induced ATP depletion, .DELTA..psi.m collapse, and apoptosis. Caspase-3 activation, usually resulting from .DELTA..psi.m collapse, was not always assocd. with As2O3-induced apoptosis. As2O3 induced PML (promyelocytic leukemia) protein degrdn. but did not modulate expression of cell cycle-related proteins, including cmyc, **retinoblastoma** protein, cyclin-dependent kinase 4, cyclin D1, and p53, or expression of differentiation-related antigens. Substantial growth inhibition and apoptosis without evidence of differentiation were induced in most malignant lymphocytic cells treated with 1-2 .mu.M As2O3. As2O3 may prove useful in the treatment of malignant lymphoproliferative disorders.

AB This study's goals were to more fully define the activation of protein tyrosine phosphorylation stimulated by muscarinic receptors, to test if this signaling process is affected by oxidative stress induced by H2O2, and to compare the effects of H2O2 on protein tyrosine phosphorylation activated by epidermal growth factor (EGF) receptors. Experiments used human **neuroblastoma** SH-SY5Y cells which express endogenous M3 muscarinic and EGF receptors. Carbachol induced time-dependent increases in phosphotyrosine immunoreactivity of several protein bands, which were quantitated, and immunoprecipitation was used to identify the adhesion-related proteins focal adhesion kinase, p130Cas/HEF1, and paxillin, and three shc adapter proteins. Carbachol-induced tyrosine phosphorylation of the adhesion-related proteins was mediated by muscarinic receptors, and was inhibited by a src family kinase inhibitor, PP1. That carbachol can activate src family kinases was indicated further by the finding that carbachol induced an increase in tyrosine phosphorylation of p120-src substrate, which was inhibited by PP1. Oxidative stress induced by H2O2 concentration dependently inhibited carbachol-induced tyrosine phosphorylation of each of the adhesion-related proteins. EGF increased the phosphotyrosine immunoreactivity of 180- and 116- kDa proteins, identified as the EGF receptor and Cbl, respectively. In contrast to the results with carbachol, H2O2 potentiated EGF-induced tyrosine phosphorylation. These results demonstrate that muscarinic receptor activation induces previously unrecognized increases in tyrosine

phosphorylation, and that this signaling process is impaired by H2O2, whereas protein tyrosine phosphorylation stimulated by EGF is increased by H2O2. Thus, oxidative stress can oppositely modulate protein tyrosine phosphorylation induced by activation of G protein-coupled and growth factor receptors in the same cells.

AB Cell-matrix interactions exert a profound influence on cell function and behavior. Our earlier observations suggested that disruption of the actin cytoskeleton results in the inhibition of phorbol ester-induced matrix metalloproteinase (MMP)-9 expression. In this study, to understand the role of protein tyrosine phosphatases in matrix metalloproteinase-9 expression, we treated **glioblastoma** cells with vanadate and phenylarsine oxide (PAO), which are inhibitors of protein tyrosine phosphatases. Vanadate and PAO inhibited expression of phorbol ester-induced MMP-9 as well as constitutive expression of matrix metalloproteinase-2 in a dose- and time-dependent fashion. An assay of the activity of phosphotyrosine phosphatase (PTPase) indicated that vanadate-treated cells had reduced PTPase activity compared with that of untreated controls. Vanadate and PAO also inhibited actin polymerization, cell spreading, migration, and invasion of glioma cells. Furthermore, elevated levels of protein tyrosine phosphorylation were observed in vanadate- and PAO-treated cells in both a concentration- and time-dependent fashion and were seen to have an inverse correlation with focal adhesion kinase protein expression. These results suggest that vanadate and PAO inhibited migration and invasion of glioma cells by their effect on the cytoskeleton and inhibition of MMP expression.

AB The white matter of the brain is vulnerable to a wide variety of toxins. Leukoencephalopathy is being increasingly recognized in a number of different patient populations. The detection of early and subtle toxin effects has been facilitated by the advent of magnetic resonance imaging, which offers better resolution of white matter than other neuroimaging

methods. Neuropathologic features of leukoencephalopathy are also becoming more completely elucidated. Injury to white matter has been described from **cranial** irradiation and **cancer** chemotherapeutic drugs, and from a number of other therapeutic agents, drugs of abuse, and environmental toxins. Many patients have reversible leukoencephalopathy, whereas others experience a progressive and irreversible course. Leukoencephalopathy is associated with neurobehavioral manifestations that may be subtle or devastating, and the syndrome of white matter dementia may result. The pathogenesis of toxic leukoencephalopathy remains largely unknown, and treatment is limited in most cases to prevention by avoidance or minimization of the toxin exposure. However, the prognosis for this syndrome may be relatively favorable because of the frequent sparing of axons even when myelin is affected. Toxic leukoencephalopathy is an emerging clinical disorder that presents the opportunity for improving clinical outcomes in a number of patient groups and for achieving a deeper understanding of the role of white matter in cognitive and emotional function.

AB A role for phosphoinositides in the endocytosis of muscarinic cholinergic receptors (mAChRs) has been investigated via inhibition of the activity of phosphatidylinositol-4-kinase (PI4K). Pretreatment of SH-SY5Y **neuroblastoma** cells with micromolar concentrations of wortmannin (WT), LY-294002, or phenylarsine oxide (PAO), three chemically distinct agents known to inhibit PI4K, resulted in both an inhibition of agonist-induced endocytosis of mAChRs and a selective reduction in the 32P-labeling of phosphatidylinositol-4-phosphate. PAO-mediated inhibition of both receptor endocytosis and phosphoinositide synthesis could be fully reversed by inclusion of the bifunctional thiol 2, 3-dimercaptopropanol. The requirement for phosphoinositide synthesis in mAChR endocytosis was independent of a role for these lipids in the maintenance of the cytoskeleton because disruption of the latter with cytochalasin D, ML-7, or colchicine failed to inhibit receptor internalization. Determination of PI4K activity in subcellular fractions of SH-SY5Y cells indicated that enzyme activity in fractions enriched in endocytic vesicles and cytosol was preferentially inhibited by WT, LY-294002, and PAO, a profile consistent with the subcellular distribution of the 110-kDa beta isoform of PI4K, as determined by Western blot analysis. Activity of PI4Kbeta present in immunoprecipitated cell lysates was inhibited >75% by inclusion of each of the three inhibitors. These results indicate that ongoing

synthesis of phosphoinositides is necessary for mAChR endocytosis and that the activity of a WT-sensitive form of PI4K, such as PI4Kbeta, is required.

AB Though a developing body of data indicates polymorphism at GST genes influences cancer susceptibility, it is unclear why a genotype is associated with one cancer but not another. We believe the GST exert a critical role in normal cell house-keeping activities. GSTM1, GSTM3 and GSTT1 influence tumorigenesis because these enzymes utilise the products of UV-induced oxidative stress. Further support for the importance of these genes in the protection of skin from UV comes from studies in systemic lupus erythematosus (Ollier et al, 1996). Thus, GSTM1 null is associated with increased anti-Ro (but not anti-La) antibodies, a phenotype associated with photosensitivity. At present there is no basis for predicting which cancers will be influenced by GST polymorphisms though other studies do indicate that the GSTs are critical in the metabolism of environmental carcinogens. For example, GSTT1 null confers an increased risk of **astrocytoma** (Hand et al, 1996). While **brain tumours** are not clearly associated with environmental pollutants, N-methyl-N-nitrosourea, processed meats and occupation have been implicated. Why GSTT1 but not GSTM1 or GSTM3 influences the risk of **astrocytoma** is unclear. GSTM3 appears a good susceptibility candidate, as some astrocytes demonstrate strong expression (Hand et al, 1996). Susceptibility to squamous cell cancer of

the larynx, a pathology associated with chronic consumption of tobacco and alcohol, is also influenced by allelism at GSTM3 (Jahnke et al, 1996). The roles of CYP2D6 and CYP1A1 are even more unclear, though the finding that systemic agents such as **arsenic** predispose to multiple BCC, suggests that CYP2D6-mediated hepatic detoxification of photosensitizing agents may be important. Importantly, the extent of altered risk conferred by genotypes is generally 2-3 fold and it is necessary to identify which other genes interact with the GST so that haplotypes associated with 10-20 fold increases in risk can be defined.

AB Curcumin, a major component of turmeric, a seasoning commonly used in Indian food, and a known antioxidant, anti-inflammatory and anti-carcinogenic agent, is a potent stimulator of the stress-induced expression of Hsp27, alphaB crystallin and Hsp70. When C6 rat glioma cells were exposed to **arsenite** (100 microM for 1 h), CdCl2 (100 microM for 1 h) or heat (42 degrees C for 30 min) in the presence of 3-10 microM curcumin, induction of the synthesis of all three proteins was markedly stimulated, as detected by specific immunoassays, Western blot analysis and Northern blot analysis. A gel mobility shift assay revealed that curcumin prolonged the stress-induced activation of the heat shock element-binding (HSE-binding) activity of heat shock transcription factor (Hsf) in the cultured cells. The stimulatory effect of curcumin on the responses to stress was also observed in BRL-3A rat liver cells and Swiss 3T3 mouse fibroblasts. Induction of Hsp27, alphaB crystallin and Hsp70 in the liver and adrenal glands of heat-stressed (42 degrees C for 20 min) rats was also enhanced by prior injection of curcumin (20 mg/kg body weight). As curcumin is a potent inhibitor of arachidonic acid metabolism, it is suggested that the mechanism of the stimulation by curcumin of the stress responses might be similar to that of salicylate, indomethacin and nordihydroguaiaretic acid.

AB BACKGROUND: Primary **brain tumors** are among the most deadly of all cancers, with a 1-year survival rate of 52%. Certain elements, such as nickel, cadmium, chromium, **arsenic**, and beryllium, are established carcinogens in other organs. Silicon and titanium are suspected carcinogens and other elements are known to promote or inhibit the rate of tumor growth. Knowledge about the carcinogenicity of these elements in the brain is limited. In this study, we investigated the potential role of these elements as risk factors for human **brain tumors**. METHODS: In a case-control study, we assessed brain biopsies from 12 patients with various types of primary **brain tumors** and in **tumor**-free **brain** tissue from 6 autopsy cases. We used energy-dispersive X-ray analysis (EDX) to determine if there were significant differences in the concentration of the study elements in **tumors** and in control **brains**. RESULTS: In a bivariate analysis, a statistically significant association was observed between the presence of **brain tumors** and the concentrations of silicon ($p = 0.01$), magnesium ($p = 0.01$), and calcium ($p = 0.03$). Zinc was also associated with a borderline significance ($p = 0.05$). No association was observed for nickel ($p = 0.74$). Although the magnitude of the observed association was estimated using multiple logistic regression analyses, the relative risk estimates were imprecise because of insufficient sample size. Further research using a larger sample size is needed to elucidate the role of these elements in human brain carcinogenesis.

OS MARPAT 127:259530

AB A method is provided for detecting and localizing malignant tumors and their metastases in tissues, which in healthy condition do not contain disturbing quantities of CCK-receptors, in the body of a human being, which comprises (i) administering a compn. comprising, in a quantity sufficient for external imaging, a labeled peptide derived from H-(Xaa)n-(Xbb)m-Tyr-Xcc-Gly-Trp-Xdd-Asp-Phe-R2, or an acid amide thereof, formed between a free amino group of an amino acid moiety and R1COOH, [R1 = C1-3 alkanoyl, arylcarbonyl, aryl-(C1-3)alkanoyl group]; or a lactam

thereof, formed between a free amino group of an amino acid moiety and a free CO2H group of another amino acid moiety; or a conjugate thereof with avidin or biotin; [(Xaa)n = 0-25 amino acid moieties selected from Ala, Leu, Asn, Dpr, Gln, Glu, Ser, Ile, Met, His, Asp, Lys, Gly, Thr, Pro, Pyr, Arg, Tyr, Trp, Val, Phe; m = 0, 1; Xbb = Asp, Dpr, Glu or Pyr, with the proviso that Xbb can only be Pyr when n = 0; Xcc, Xdd = Met, Leu, Nle;; R2 = OH, acetoxy, amino]; and thereupon (ii) subjecting said being to external imaging, by radioactive scanning or by magnetic resonance imaging, to det. the targeted sites in the body. Also provided is a method for the therapeutic treatment of malignant tumors by administration of the above-defined peptide, labeled for this purpose. Further provided are a method for labeling of the peptide compds., a pharmaceutical compn. to be used for detection, a pharmaceutical compn. to be used for therapy, and a kit for prepg. a radiopharmaceutical compn. The ligands of the invention specifically recognize CCK-B receptors. The methodol. of the invention is useful for detection of tumors which are difficult to characterize, e.g. small-cell lung carcinoma and medullary thyroid carcinoma.

AB We have recently shown MRP gene expression to be a powerful prognostic marker in **neuroblastoma** and suggested that the N-myc oncogene may regulate expression of this drug resistance gene (NEJM; 334:231 1996). The effect of N-myc down-regulation on MRP expression and response to cytotoxic drugs was investigated in **neuroblastoma** NBL-S cells transfected with N-myc antisense RNA constructs. The level of MRP expression was decreased in two independent antisense clones, as determined by RNA-PCR, Northern analysis and immunofluorescence. In contrast, the level of P-glycoprotein expression was unchanged. Concomitant with MRP down-regulation, both antisense clones demonstrated significantly increased sensitivity to the MRP substrates vincristine, doxorubicin, sodium **arsenate** and potassium antimony tartrate. In contrast, the response of the antisense clones to either Taxol or cisplatin, neither of which are effective MRP substrates, was unchanged. The present results suggest that N-myc can influence cytotoxic drug response via regulation of MRP gene expression, thus providing an explanation for the established association between N-myc gene amplification and poor outcome in **neuroblastoma**.

AB Soft tissue sarcoma (STS) accounts for approximately 1% of all cancers diagnosed annually in the United States. Population-based data from Connecticut covering the years 1935-1989 have shown an increasing incidence of STS in both genders, with a greater increase among men than women. The recent increase in acquired immune deficiency syndrome-related Kaposi's sarcoma does not explain the upward trend in STS, dating back decades. Etiologic heterogeneity is suggested by epidemiologic variations that have been observed by subsite and cell type. Among the environmental factors associated with STS are external radiation therapy, Thorotrast, **arsenical** pesticides and medications, phenoxyherbicides, dioxin, vinyl chloride, immunosuppressive drugs, alkylating agents, androgen-anabolic steroids, human immunodeficiency virus, and human herpes virus type 8. In addition, STS occurs excessively among persons with certain heritable states including **retinoblastoma**, Li-Fraumeni syndrome, Gardner's syndrome, Werner's syndrome, nevoid basal cell carcinoma syndrome, neurofibromatosis type 1, and some immunodeficiency syndromes. These risk factors account for a minority of STS cases but provide leads for further epidemiologic and interdisciplinary studies into the genetic and environmental determinants of various forms of STS.

AB The development of more cost-effective light sources for photodynamic therapy of **brain tumors** would be of benefit for both research and clinical applications. In this study, the use of light-emitting diode arrays for photodynamic therapy of **brain tumors** with Photofrin porfimer sodium was investigated. An inflatable balloon device with a light-emitting diode (LED) tip was constructed. These LEDs are based on the new semiconductor aluminum gallium **arsenide**. They can emit broad-spectrum red light at high power levels with a peak wavelength of 677 nm and a bandwidth of 25 nm. The balloon was inflated with 0.1% intralipid, which served as a light-scattering medium. Measurements of light flux at several points showed a high degree of light dispersion. The spectral emission of this probe was then compared with the absorption spectrum of Photofrin. This analysis showed that the light absorbed by Photofrin with the use of the LED source was 27.5% of that absorbed with the use of the monochromatic 630-nm light. Thus, to achieve an energy light dose equivalent to that of a laser light source, the LED light output must be increased by a factor of 3.63. This need for additional energy is the difference between a 630- and 677-nm absorption of Photofrin. Using the LED probe and the laser balloon adapter, a comparison of brain stem toxicity in canines was conducted. LED and laser light showed the same signs of toxicity at equivalent light energy and Photofrin doses. The maximal tolerated dose of Photofrin was 1.6 mg/kg, using 100 J/cm2 of light energy administered by laser or LED. This study concludes that LEDs are a suitable light source for photodynamic therapy of **brain tumors** with Photofrin. In addition, LEDs have the potential to be highly efficient light sources for second-generation photosensitizers with absorption wavelengths closer to the LED peak emission.

AB Toxic elements As and Th, six rare-earth elemental profiles of **brain tumor** tissues from 16 patients of **astrocytomas** (grade I-III), and normal human brain tissues of 18 male, age-matched autopsies serving as controls have been studied by radiochemical neutron activation analysis. P-204 [di(2-ethylhexyl) phosphate] extraction chromatography column was used for group separation of rare-earth element (REE) by one step. Compared with the normal brain tissues, the analytical results showed that the concentrations of Th, La, Ce, Gd, and Lu were significantly higher in tumor tissues ($P < 0.01$ or 0.001). The possible effects of REE on tumor cell were discussed.

AB The fundamental event underlying scrapie infection seems to be a conformational change in the prion protein. To investigate proteins that might feature in the conversion of the cellular prion protein (PrPC) into the scrapie isoform (PrPSc), the authors examd. mouse **neuroblastoma** N2a cells for the expression and cellular distribution of heat shock proteins (Hsps), some of which function as mol. chaperones. In scrapie-infected N2a (ScN2a) cells, Hsp72 and Hsp28 were not induced by heat shock, sodium **arsenite**, or an amino acid analog, in contrast to uninfected control N2a cells, while other inducible Hsps were increased by these treatments. Following heat shock of the N2a cells, constitutively expressed Hsp73 was translocated from the cytoplasm into the nucleus and nucleolus. In contrast, the distribution of Hsp73 in ScN2a cells was not altered by heat shock; the discrete cytoplasmic structures contg. Hsp73 were largely resistant to detergent extn. These alterations in the expression and subcellular translocation of specific Hsps in ScN2a cells may reflect the cellular response to the accumulation of PrPSc. Whether any of these Hsps feature in the conversion of PrPC into PrPSc or the pathogenesis of prion diseases remains to be established.

AB **Arsenic** and selenium possess several biol. functions and may act antagonistically. Selenium, essential for man, is an integral part of the enzyme glutathione peroxidase. It is used therapeutically for the treatment of acute pancreatitis and has demonstrated anticarcinogenic effects. **Arsenic** seems to catalyze glutathione biosynthesis and to be involved in the metab. of arginine, membrane phospholipids, and zinc. Hemodialyzed patients often suffer from trace element imbalances. To check their As and Se status, the authors collected sera from patients and healthy subjects. Sera were mineralized and As and Se detd. by hydride generation AAS. The patients had lower serum concns. of As (8.1 ng/mL) than controls (10.5 ng/mL). Selenium concns. (42 ng/mL) were also lower in dialysis patients than in the control group (64 ng/mL). **Cancer**, cardiomyopathy, diabetes, vascular and **central nervous system** (CNS) diseases and diet may cause markedly decreased Se concns. Low As concns. were found only in patients, suffering from CNS-diseases. Comorbid conditions such as high blood pressure and hepatic damages did not correlate with As and Se concns. No definite relations were found between As or Se status and age, sex, wt. or smoking habits. Hemodialysis appears to disturb not only Se but also As homeostasis. As and Se serum levels are influenced by diseases assocd. with hemodialysis. The results suggest that As could play an essential role for man. Se supplementation for dialysis patients should be considered to improve their general health status and to prolong their life.

AB The responses of two low-mol.-wt. stress proteins, .alpha.B crystallin and HSP28, to various types of stress were detd. quant. by specific immunoassays in a human **glioblastoma** cell line (U118 MG). Levels of .alpha.B crystallin (2-4 ng/mg protein) and HSP28 (1-1.5 .mu.g/mg protein) in the sol. fraction from cells that had been cultured at 37.degree. increased about 100-fold and 3-fold, resp., within 24 h after heat treatment for 15 min at 45.degree., with a temporary decrease, due to redistribution to the insol. fraction, during the heat treatment. Exposure of cells to **arsenite** ($NaAsO_2$, 100 .mu.M for 1 h) also induced the two proteins with a time course similar to that obsd. after heat stress, but without a decrease during the stress period. L-Azetidine-2-carboxylate (5 mM for 5 h) was also effective in inducing the two proteins, but to a lesser extent. Other chems., including $CdCl_2$, $ZnCl_2$, $AlCl_3$, ethanol, caffeine, nicotine, NaN_3, dibutyryl 3',5'-cAMP, forskolin, and a phorbol ester, did not induce the two proteins. Expression of .alpha.B crystallin and HSP28 mRNAs in cells was enhanced

after heat stress and after exposure to **arsenite**. When cells were challenged with heat stress in the presence of **arsenite**, the effect on the induction of the two proteins was synergistic. Ethanol (1-2%) enhanced the responses to heat stress or **arsenite** stress. Glycerol (10% or 1.36 M), added to the culture medium during the stress period, completely blocked the expression of the mRNA for .alpha.B crystallin and the induction of the two proteins by heat stress, but not that by **arsenite** stress. These results indicate that the two low-mol.-wt. stress proteins, .alpha.B crystallin and HSP28, respond analogously to heat and chem. stressors in U118 MG cells, but suggest that the events assocd. with activation of the heat shock genes by heat stress are different from those assocd. with the activation by chem. (**arsenite**) stress.

AB The major inducible .apprx.70 kDa heat shock proteins (i.e., 72 kDa HSP) are incorporated into the biol. active light nucleocapsid (L-NC) variant of canine distemper virus (CDV). In vitro induction of the cellular stress response, characterized by elevated cytoplasmic and intranuclear 72 kDa HSP, enhanced the L-NC expression in mink lung cells supporting stable persistent infection by raccoon-origin CDV. Increases in L-NC correlated with the increased viral RNA prodn. in cell-free transcriptional assays. The enhanced prodn. of viral transcripts within infected cells following stress response induction was confirmed by slot blot and Northern blot anal. of total cellular RNA and was reflected in increased total viral protein prodn. Post-shock increases in viral fusion (F) gene transcripts and F protein were assocd. with dramatic increases in viral cytopathic effect. A modest induction of cell-free infectious viral progeny was also documented. A similar effect of the cellular stress response upon viral protein expression, cytopathic effect, and cell-free infectious progeny release was demonstrated in murine **neuroblastoma** cells persistently infected with a canine CDV isolate. Alterations of the persistent viral phenotype were independent of the specific mechanism of stress-response induction (heat or sodium **arsenite**), supporting the role of the stress response and not of a particular stressor in mediating these changes. The results document the ability of the cellular environment to alter persistent viral RNA metab., thereby altering the infection phenotype.
AB The major inducible .apprx.70 kDa heat shock proteins (i.e., 72 kDa HSP) are incorporated into the biol. active light nucleocapsid (L-NC) variant of canine distemper virus (CDV). In vitro induction of the cellular stress response, characterized by elevated cytoplasmic and intranuclear 72 kDa HSP, enhanced the L-NC expression in mink lung cells supporting stable persistent infection by raccoon-origin CDV. Increases in L-NC correlated with the increased viral RNA prodn. in cell-free transcriptional assays. The enhanced prodn. of viral transcripts within infected cells following stress response induction was confirmed by slot blot and Northern blot anal. of total cellular RNA and was reflected in increased total viral protein prodn. Post-shock increases in viral fusion (F) gene transcripts and F protein were assocd. with dramatic increases in viral cytopathic effect. A modest induction of cell-free infectious viral progeny was also documented. A similar effect of the cellular stress response upon viral protein expression, cytopathic effect, and cell-free infectious progeny release was demonstrated in murine **neuroblastoma** cells persistently infected with a canine CDV isolate. Alterations of the persistent viral phenotype were independent of the specific mechanism of stress-response induction (heat or sodium **arsenite**), supporting the role of the stress response and not of a particular stressor in mediating these changes. The results document the ability of the cellular

environment to alter persistent viral RNA metab., thereby altering the infection phenotype.

AB Workers in the Swedish art glass industry are exposed to a variety of hazardous chemicals, some of which are known carcinogens. Most of these substances are components of the glass batch (ie, the mixture of substances used to make glass; eg, compounds of **arsenic**, antimony, lead, cadmium, chromium, and nickel). Furthermore, large amounts of hydrofluoric acid and sulfuric acid are used in the polishing process and, in the past, equipment made of asbestos was used for handling hot glass. Many of these chemicals are found not only within the glassworks themselves, but have also been emitted to the environment, causing general concerns about health hazards among people living in the vicinity of glassworks. Some glass workers are also exposed to combustion products and constant heat stress when working close to the glass furnaces. The present studies show that Swedish art glass workers run increased risks of dying from cancer of the stomach, colon and lung and from cardiovascular diseases. In one of the studies, increased risks were also observed for prostate and pharynx cancer and for cerebrovascular diseases. The worker category showing the highest cancer risks was the glass blowers. The exposure route for this category of workers might be through both inhalation of airborne substances and ingestion of particles entering the mouth by way of the blowpipe. These possibilities are supported by hygienic measurements, including analysis of slag samples from inside the blowpipes. The present studies were initiated due to concern about cancer risks expressed by people living close to glassworks, but the only increased risk found in this population was a cluster of **brain cancers**. Glass workers represent a large part of the population living in the vicinity of the glassworks, where the cluster of **brain cancers** occurred, and because of this, registry-based studies of Swedish glass workers seem to have spuriously indicated an occupational risk in this respect. Although the detected cluster of **brain cancers** might have its origin in some industrial discharge from the glassworks, the chemicals predominating in the emissions are not known to cause **brain cancers**, and other factors might be involved as well. (Abstract shortened by University Microfilms International)

AB PCR and Southern blot analyses demonstrate that mRNA for heme oxygenase (HO), a well known "stress protein" in a number of tissues, is present in human retina. Western and northern blots show that the protein and mRNA are also expressed in human Y-79 **retinoblastoma** cells in culture and that the HO enzyme is rapidly induced by its substrate, heme. Moreover, HO is also induced by two chemicals, sodium **arsenite** and menadione, that act as agents of oxidative stress. HO is the regulatory enzyme in the heme degradative pathway and an increase in its activity could lead to the accumulation of bilirubin, an antioxidant, in the cell at the expense of heme, a prooxidant. The HO pathway may thus be of importance in protecting the retina against oxidative stress in vivo. Moreover, the Y-79 culture system should provide an excellent model for use in examining stress mechanisms in retinal cells at a molecular level.

AB The authors review the available evidence on cancer risk associated with exposure to agricultural chemicals. Agricultural workers generally show a lower cancer mortality compared with other occupational categories. This observation is currently believed to be due to lower cigarette consumption. However, for some types of tumours (lymphoma, leukaemia, myeloma, soft tissue sarcoma, skin, prostate, **brain** and stomach **tumours**), mortality is higher among agricultural workers. The only chemical substances used in agriculture for which the IARC Monographs have established the existence of sufficient evidence of carcinogenicity for man are **arsenical** compounds and mineral oils; for other substances there is clear evidence of carcinogenicity in experimental animals, mostly in the absence of human data. In the case of exposure to phenoxyacetic herbicides, the available epidemiological evidence is contradictory, with excesses of non-Hodgkin lymphoma and soft tissue sarcoma reported in some studies but not in others. Cohort studies have been performed among insecticide production workers and spray operators (with excesses of lung tumour), and among grain processing workers (with excesses of non-Hodgkin lymphoma in particular). A number of case-control studies are also available, especially concerning tumours of the lymphatic and haemopoietic systems and ovarian tumours.

AB In an effort to better understand the epidemiology of cancer in Zaire, a retrospective review of biopsy-proven malignant tumors was undertaken. Of 188 biopsies taken from children aged 0-15 years over a 4.5 year period, 73 (39%) revealed malignancy. Fifty-six percent of patients with malignant tumors were boys. Lymphoma was the most common tumor (28

patients, 15 with Burkitt's Lymphoma). Sarcoma (15 patients), carcinoma (8 patients), Wilms' Tumor (6 patients), and **retinoblastoma** (5 patients) were also seen. Lymphomas were most heavily represented in the first 5 years of life, while sarcoma and carcinoma accounted for most of the malignancies in children after 10 years of age. Lymphomas and sarcomas are relatively more common in Zaire than in North America and Europe, while leukemia and **central nervous system tumors** are notably less common in Zaire. In view of current limitations on health care in rural Zaire, cancer care should be directed toward early diagnosis, quick referral for appropriate surgical care, and use of the limited **arsenal** of chemotherapy.

AB A conditioning treatment of 30 min at 42 degrees C or 43 degrees C, followed by a 4-h recovery period at 37 degrees C, induces thermotolerance state in the cytoskeleton of Reuber H35 hepatoma cells and N2A **neuroblastoma** cells. Evidence for the involvement of heat shock proteins in the development of thermotolerance in the cytoskeleton has been obtained from the following observations: only those conditioning treatments inducing the enhanced synthesis of heat shock proteins (HSPs) are able to induce the heat-resistant state of the cytoskeleton; prevention of HSP synthesis by actinomycin D or cycloheximide also prevents the acquisition of thermotolerance in the cytoskeleton; an alternative inducer of HSP synthesis, sodium **arsenite**, is also able to induce the cytoskeletal thermotolerance; the kinetics of development and disappearance of thermotolerance in the cytoskeleton is parallel to the kinetics of accumulation and decay of HSPs. The possible function of HSPs in the heat-resistant cytoskeleton of H35 hepatoma and N2A **neuroblastoma** cells is discussed.

AB By using affinity-purified antibodies, the 84,000-dalton heat-shock protein (hsp) was localized in mouse N2A **neuroblastoma** cells by immunocytochem. techniques. Immunofluorescence microscopy showed that hsp84 was present both in the cytoplasm and nucleus. The nucleoli were unlabeled. Immuno-Au labeling on ultrathin cyosections revealed that hsp84 was evenly distributed throughout the entire cytoplasm. No preferential assocn. of hsp84 with the plasma membrane or with membranes from organelles was obsd. In the nucleus the hsp84 was present in both the euchromatin and heterochromatin. In the nucleolus only the fibrillar part was labeled and virtually no Au particles were obsd. in the granular part. A long-term hyperthermic treatment of 3 h at 42.5.degree. induced an accumulation of hsp84 inside the nucleus. No alterations in hsp84 distribution were obsd. during treatment of the cells with 75 .mu.M Na **arsenite** for 3 h. Drastic alterations were obsd. in the nucleoli after both stress treatments. The granular part had totally disappeared and only remnants of the fibrillar part, which contained hsp84, were found. Besides the nuclear accumulations of hsp84 during heat shock, no addnl. changes in the hsp84 location in stressed cells were obsd. During recovery from the heat shock by replacing the cells at 37.degree., a decrease in the nuclear location of hsp84 was obsd., indicating the reversibility of this process.

AB In the human lymphocyte, desensitization of the beta-adrenergic receptor-adenylate cyclase complex is associated with sequestration of the receptor as well as a change in photolabeling of beta-receptor proteins. Thus, desensitization of the lymphocyte beta-adrenergic receptor-adenylate cyclase system is associated with a selective reduction in the photoaffinity labeling of an Mr approximately equal to 55,000 beta-adrenergic receptor-binding site as compared to an Mr approximately equal to 68,000 beta-adrenergic receptor-binding moiety. In order to examine the relationship between sequestration and reduction in labeling of the Mr approximately equal to 55,000 peptide, we have studied the effect of phenylarsine oxide (an inhibitor of beta-receptor sequestration in **astrocytoma** cells) on agonist-induced desensitization of the beta-adrenergic receptor-adenylate cyclase system in circulating lymphocytes. Incubation of cells with phenylarsine oxide prior to exposure to agonists did not block the consequent reduction in isoproterenol-stimulated adenylate cyclase activity. However, sequestration of the receptor, as assessed by a decrease in accessibility of beta-adrenergic receptors on intact cells to hydrophilic receptor ligands, is blocked by phenylarsine oxide. Thus, the agonist-induced reduction in binding of the hydrophilic beta-adrenergic receptor ligand CGP-12177 was blocked by phenylarsine oxide (without phenylarsine oxide, 57 +/- 6% of control, with phenylarsine oxide, 97 +/- 3% of control). Photolabeling studies with [125I]iodocyanopindolol diazirine revealed that phenylarsine oxide pretreatment also blocked the selective loss in labeling of the Mr approximately equal to 55,000 beta-adrenergic receptor protein. These data suggest that agonist-induced alterations in the photolabeling pattern of the lymphocyte beta-adrenergic receptor that occur with desensitization closely parallel the apparent sequestration of beta-adrenergic receptors but can be dissociated from the initial desensitization phenomenon.
AB . . . Mr approximately equal to 55,000 peptide, we have studied the effect of phenylarsine oxide (an inhibitor of beta-receptor sequestration in **astrocytoma** cells) on agonist-induced desensitization of the beta-adrenergic receptor-adenylate cyclase system in circulating lymphocytes. AB The ligand-induced internalization of .beta.-adrenergic receptors and the receptor-mediated internalization of epidermal growth factor [62229-50-9] were blocked, under similar conditions, by phenylarsine oxide (PAO) [637-03-6] in human **astrocytoma** cells (1321N1). The inhibition was not prevented or reversed by monofunctional SH agents such as 2-mercaptoethanol or glutathione; however, the inhibitory action of PAO was blocked and reversed by bifunctional thiols such as 2,3-dimercaptoethanol or dithiothreitol. The results are consistent with the interaction of PAO with vicinal SH groups to form a stable ring structure. PAO did not prevent (-)-isoproterenol [51-31-0]-induced uncoupling (desensitization) of .beta.-adrenergic receptors even though receptor internalization was completely blocked. The effects of PAO on receptor internalization could not be explained by any action of the trivalent **arsenical** to lower ATP levels. Ligand binding to both receptors was not detectably altered by PAO under conditions selective for inhibition for endocytosis. The results suggest a common mechanism for internalization of .beta.-adrenergic receptors and epidermal growth factor by a process that involves vicinal SH groups.

AB A clone of murine **neuroblastoma** (N1E-115) was shown to have functional receptors for the nonapeptide bradykinin. These receptors mediated a large, rapid (about 1 min to peak) and calcium-dependent increase in cyclic GMP. The median effective concentration (EC50) averaged 1.4 nM. In addition, this event was inhibited by quinacrine, 5,8,11,14-eicosatetraynoic acid, and nordihydroguaiaretic acid, suggesting involvement of phospholipase A2 with subsequent formation of lipoxygenase metabolites of arachidonic acid. [3H]Bradykinin binding to intact cells, investigated under conditions nearly identical to those used in the cyclic GMP assay, yielded binding sites with K(D)s of 0.83 pM, 1.0 nM, and 4.9 nM with respective B(max) values of 12, 160, and 250 fmol/106 cells. Apparently, the cyclic GMP response was associated with the binding site in which the K(D) = 1.0 nM. Peptide analogs of bradykinin stimulated cyclic GMP with EC50s nearly identical to their respective K(D)s determined in binding assays with [3H]bradykinin, thus providing evidence for receptor specificity of this response. This finding of a biochemical response of bradykinin promises to make N1E-115 cells a convenient model system for study of neuronal bradykinin receptors.

AB The authors report an observation of african trypanosomiasis due to Trypanosoma Gambiense, clinical signs included massive and progressive hemiplegia, papillary edema and vascular shift from median line at arteriography. These pseudo tumoral clinical features are unusual in this disease. Asymetrical heterogenous hypodensities of the centrum semioval are dominant in the initial CT scanner aspect. The confrontation of CT scanner images to the clinical and evolutive data suggests the presence of associated cerebral edema and demyelination. With treatment, hypodensities were regressing while images of subcortical atrophy appeared. Lastly, in spite of severe general signs and the importance of neurological deficit, **arsenical** treatment associated with high doses of corticotherapy lead to a rapid improvement.

AB Geographical pathology points to environmental factors in cancer and helps estimate their potential magnitude. An occupational contribution was established by 1972 for cancer of the mouth, lung, bladder, and skin. Additionally partly based on geographical pathology, an occupational etiology is accepted for some **cancer** of nasopharynx, **brain**, liver, pleura, nasal sinus, bone and bone marrow, and possibly stomach. For identifying new occupational factors based on geographical comparisons, both an optimal size of work force to be

followed-up and a sufficiently high proportion of work force in the geographical unit's population are necessary. Hypothetical variations based on 30-year follow-up of asbestos workers illustrate this. Cancer surveys and registries can greatly facilitate detection of occupational cancer. Evidence for occupational factors in the geographical pathology of lymphosarcoma is briefly summarized; but no conclusions are reached.

AB The use of radiopharmaceuticals in myeloscintigraphy, cisternography, cerebrospinal fluid circulatory studies, vitamin B12 resorption assays, cerebral hemorrhage localization, and **tumor** diagnosis is reviewed. **Brain** scintigraphy is uncomplicated with TC99m, which has a low radiation load and a short half-life; whole body exposure after administration of 10 mCi iv is only 0.1 rads. Tumor localization is also more accurate than that after carotid angiography. The radionuclide is especially indicated for the presentation of space-displacing hemispheric masses and subdural hematomas, but not well indicated for infratentorial tumors or poorly delimited masses at the skull base. In the latter area, an improved contrast between tumor focus and adjacent tissue can be achieved by techneticum-labeled compounds which are rapidly excreted by the kidney, such as DTPA (diethylenetriaminopentaacetic acid) or citrate complexes. Other diagnostic agents include radioiodinated human serum albumin, radiomercurated chlormerodrin, Bi206 nitrate, As-74 **arsenite/arsenate**, and Cu64-EDTA (ethylenediaminetetraacetic acid). All of these penetrate tumor foci indifferently. Further improvement in differentiating between tumor, inflammatory focus, or infarction can be obtained with tumor-specific agents, such as Ga67 citrate in carrier-free form or labeled bleomycin. These compounds are taken up actively by viable tumor cells, but not by necrotic tissue. (15 refs)

AB Since the introduction of computer tomography in 1972, this new method has rapidly established itself as an extremely valuable instrument in the neuro radiologic **arsenal**. This article presents the results of the first 200 examinations at the department of neuro radiology in Umea. The results are in close agreement with previous experiences. The method has thus proved to be a safe aid to, i.e., differential diagnosis of intracerebral hemorrhage and infarct. It has also proved highly suitable for the investigation of traumatic lesions. Tumor diagnosis can be very far reaching, especially if the so called contrast enhancement is applied, and the agreement between the findings in computer tomography and encephalography plus angiography respectively was found to be extremely good. The number of the latter examinations has reduced considerably with increased experience of the new method.

AB Although polyvinyl chloride has been produced from vinyl chlride monomer for more than 40 years, recognition of toxicity among vinyl chloride polymerization workers is more recent. In the mid 1960s, workers involved in cleaning polymerization tanks were found to have acro-osteolysis. In 1974, the same population of workers was found to be at risk for an unusual type of hepatic fibrosis and angiosarcoma of the liver. We describe two cases of vinyl chloride-associated liver injury, one of hepatic fibrosis and one of angiosarcoma. Histologic features of these lesions are similar to the hepatic fibrosis and angiosarcomas resulting from chronic exposure to inorganic **arsenicals**. Preliminary studies suggest that the toxicity of vinyl chloride may result from formation, during high-dose exposure, of active metabolites by mixed function oxidases of the liver. Epidemiologic studies indicate an increased incidence not only of liver disease, but also of **cancers** of the **brain**, lung, and possibly other organs.

AB This article is the second part of a review of this subject. The first part was published a week earlier in the Jan. 15 issue of the same journal (New England J. Med., 294: 143-148, 1974). In this first part the following subjects were summarized: Uremic encephalopathy and its manifestations of asterixis, tremor, myoclonus, tetany, motor abnormalities, convulsions, electroencephalographic findings; the treatment of convulsions; cerebrospinal fluid findings in uremic encepholopathy, and the pathophysiology of this condition. This second part is concerned with uremic neuropathy and the neurological complications of dialysis and renal transplantations. Uremic neuropathy is present in at least 65 percent of patients who are about to begin dialysis for chronic renal failure and may be the most common neurological complication of chronic uremia. It is described as a distal, symmetrical syndrome, affecting the lower extremities more than the upper and is clinically similar to other toxic neuropathies. The 'restless legs

syndrome' is common and likely a prodromal symptom. Burning of the feet similar to that seen in alcoholics and **arsenical** neuropathy is an early symptom and muscle cramps are common. Most patients with uremic neuropathy will improve on dialysis although severe cases seldom recover completely. Renal transplantation affords a much better prognosis; most patients recover in 6 to 12 months. Slowing of nerve conduction occurs frequently in uremia without other symptoms or signs of neuropathy. The pathology of uremic neuropathy is focused on destruction of the axon with secondary demyelinization. Consequently, motor nerve conduction velocity is not a dependable guide to the severity of the neuropathy. The secondary segmental loss of myelin is consequential to the axonal destruction which in turn, likely represents metabolic failure of the perikaryon. (Voris - Chicago, Ill.)

AB Cr .beta.-glycerophosphate labeled with 51Cr accumulates actively in mice with transplanted ependymal tumors. The expts. reported demostrate that radiolabels other than 51Cr can be incorporated into this particular Cr complex without significantly altering its metabolic behavior. Radioarsenic was used effectively for this purpose.
TI Uptake of radioarsenic-labeled chromic .beta.-glycerophosphate by experimental **brain tumors**

AB At the 7th Conference of the European Research Committee for the Protection of the Population from chronic toxic environmental damages ('Eurotox') held in Brussels (June 3-5, 1964), R. Truhaut reported on the carcinogenic action of some inorganic substances (nickel carbonyl, metallic nickel, cadmium, **arsenic**, etc). A. La fontaine discussed the contamination of air, water and food by radioactive substances. P. Shubik found that the amount of tar in charcoal-broiled steaks was equivalent to that found in 700 cigarettes. E. Bolyand reported on estrogenic substances in plants and their use in cosmetics. F. Dickens discussed the carcinogenic properties of some lactones, including aflatoxin (see CRA 1(1):Number 72; ibid, (5):Number 872, 1963; and ibid, 2(3):Number 484, 1964). J. Mc. L. Philip reported on the toxic effect of aflatoxin (A). In young rats fed peanut meal for more than 30 wk, liver tumors, and some lung metastases, were found. E. Le Breton found 200 microg of angstroms did not cause embryonal malformation in rats; after partial hepatectomy 50 microg angstroms inhibited liver regeneration of rats; biochemical studies showed blockage of RNA and DNA synthesis. Y. Ueno isolated luteoskyrene and a chloride-containing peptide from Penicillium islandicum, both of which caused malignant hepatic tumors when admin to rats; biochemical studies revealed the inhibition of respiration, oxidative phosphorylation and glycogen synthesis. F. S. C. Roe discussed the carcinogenic effect of some volatile oils (orange, lemon, eucalyptus etc). P. N. Magee showed that the alkaloids (cyclic esters of hydroxylated 3,4-unsaturated pyrrolizidines with branching side chain) from Senecio jacobaea caused liver cancer. 'Cycasin' (C; methyl-azoxymethanol-glycoside of Cycas plants) produced carcinomas of the kidney and liver in rats. G. L. Lacquer found that C was not carcinogenic to germfree rats by its aglycone (methyl-azoxy-methanol) caused liver cancer in guinea pigs and intestinal carcinomas in rats. H. Druckrey showed that methylnitrosourea caused **malignant tumors** of **brain** and **spinal cord** in rats. Azoethane was found to be carcinogenic.

AB The use of isotopic tracer methods in studies of the brain is discussed. The basic technique for localization of focal intracranial disease by using a positron scanner on each side of the head to detect the 2 annihilation quanta from positron-electron interactions is described. The advantages of positron scanning include high sensitivity at high resoln., very low background effects, uniform response, and As74 appears to be preferable to most materials used for external **brain tumor** localization. The advantages and disadvantages of radioactive isotopes of As, Cu, F, Rb, Zr, I, and Ga were studied. Direct clin. applications of positron scanning are discussed.

NOVELTY - Treatment of neuropathic pain involves administering 4-aryl-4-piperidinecarbinols (I) or (II).

DETAILED DESCRIPTION - Treatment of neuropathic pain involves administering 4-aryl-4-piperidinecarbinols of formula (I) or (II) or their salts or N-oxides.

m = 1-3;

R1 = CH3, C2H5, n-C3H7 or allyl; or

R1+R2 = 3-4C alkylene;

R2, R3 = H or 1-4C alkyl; or

R2+R3 = 3-6C alkylene;

R4 = phenyl (optionally substituted by X), 2-, 3- or 4-biphenyl (optionally substituted by 1-2 F, Cl, 1-12C alkyl, 1-12C perfluoroalkyl, 1-12C alkoxy, aryloxy, 1-12C alkylthio, 1-12C perfluoroalkoxy, 6-12C arylthio, 1-12C perfluoroalkylthio or di(1-12C alkyl)amino), 1- or 2-naphthyl (optionally substituted by 1-2 X), 2-, 3- or 4-pyridyl or 2-, 3- or 4-pyrrolyl (optionally substituted by 1-3 1-4C alkyl), 2- or 3-thienyl (optionally substituted by Cl, Br or 1-4C alkyl) or 2- or 3-benzothienyl or benzofuryl (optionally substituted by Cl, Br or CF3);

X = F, Cl, Br, 1-12C perfluoroalkyl, 1-12C alkyl, 1-12C alkylamino, di(1-12C alkyl)amino, 1-12C alkylthio, alkoxy or phenoxy;

R5 = 1-4C alkyl; or

R5+R6 = optionally branched 3-11C alkylene;

R6 = H or 1-4C alkyl;

R7 = H, 1-4C alkyl, 1-4C alkanoyl or benzyl;

X1, X2 = O or NR'2;

R'1 = H, alkyl, 1-6C alkyl (optionally substituted), alkenyl, alkynyl, acyl, C(O)R'5, C(O)NR'5R'6, C(O)OR'5, C(O)SR'5, C(S)R'5, C(S)NR'5R'6, C(S)OR'5, C(S)SR'5, C(NR'7)R'5, C(NR'7)R'5R'6, C(NR'7)OR'5, C(NR'7)SR'5 or phosphate; and

R'2, R'5-R'7 = H or alkyl;

provided that:

(i) when R1, R5, R6 = Me and R2, R3 = H then R4 is not 3,4-F2C6H3, 3,4-Cl2C6H3, para-t-butylphenyl, 2,3-(MeO)2C6H3, 2,5-(MeO)2C6H3 or 3-pyridyl; and

(ii) when R1, R5, R6 = Me or R5+R6 = -(CH2)6 or -(CH2)7, then R4 is not 3-(MeO)C6H4.

ACTIVITY - Analgesic; Neuroprotective.

MECHANISM OF ACTION - Serotonin Uptake Inhibitor; Norepinephrine Uptake Inhibitor; Dopamine Uptake Inhibitor; Ectopic Discharge Inhibitor. In tests, 4-(3'-thienyl)- alpha , alpha ,1-trimethyl-4-piperidinemethanol (IIa) inhibited rat synaptosomal 5-HT and NE reuptake with IC50 values of

120 and 223 nM, respectively.

USE - (I) And (II) are useful for the treatment and prophylaxis of neuropathic pain caused by carpal tunnel syndrome, cervical or lumbar radiculopathy, complex regional pain syndrome, spinal cord injury, stump pain, metabolic or toxic disease, endocrinologic disorder (e.g. diabetes mellitus, diabetic neuropathy, amyloidosis and amyloid polyneuropathy), malignant tumor, eosinophilia-myalgia syndrome, monoclonal gammopathy, multiple sclerosis, stroke, postherpetic neuralgia, neuropathy with monoclonal protein, vasculitic neuropathy, neuropathy associated with Guillain-Barre syndrome, neuropathy associated with Fabry's disease, entrapment due to anatomic abnormality, trigeminal, **CNS** neuralgia, **malignancy**, inflammatory condition, autoimmune disorder (e.g. demyelinating inflammatory disorder, rheumatoid arthritis, systemic lupus erythematosus and Sjogren's syndrome), iodopathic distal small-fiber neuropathy, toxin and drug (e.g. **arsenic**, lead, mercury, thallium, alcohol), vincristine, cisplatinum and dideoxynucleoside), dietary or absorption, abnormality, immuno-globulinemia, hereditary abnormality, mastectomy, amputation, viral infection (e.g. HIV infection or herpes) in human (claimed); also for treating neuropathic dysfunction.

ADVANTAGE - (I) And (II) do not show significant activity at mu , kappa, delta or sigma receptor sites in the brain; does not inhibit prostaglandin synthetase; does not exhibit an antiinflammatory effect in vivo; do not exhibit anticholinergic side effects, sedation or motor impairment; lacks additive or respiratory depressant properties; and inhibit ectopic discharge in the peripheral nervous system pathway, in the dorsal-root-ganglion cells of damaged afferent axons.

AB Arsenic trioxide (As2O3) at low concns. (1-10 .mu.M) is effective in the treatment of acute promyelocytic leukemia (APL) and lymphoma and is in clin. trials for treatment of solid tumors. Paclitaxel, an antimicrotubule agent, is highly efficacious in the treatment of adult tumors and is in clin. evaluation in childhood tumors. This study is the first to investigate the combination of arsenic and paclitaxel in the range of clin. achievable concns. We found that the simultaneous combination was antagonistic on proliferation of the neuroblastoma SK-N-SH cell line by using the combination index (CI) method. Moreover, a

40.+-.5% decrease in paclitaxel-induced apoptosis in cells co-treated with As2O3 confirmed the antagonism. The mechanism of antagonism was studied at the cellular level with 200 nM paclitaxel, twice the ic50 value, and with 1 .mu.M As2O3 which administered singly did not affect cell survival or the microtubule network. As2O3 antagonized the effects of paclitaxel on tubulin and microtubules. Paclitaxel-induced mitotic block was decreased by 20.+-.2% and bundles induced by 200 nM paclitaxel were less condensed in the presence of 1 .mu.M As2O3. As2O3 (10-200 .mu.M) induced a concn.-dependent inhibition of tubulin polymn. in vitro which was maintained in presence of paclitaxel. Spectrophotometric and spectrofluorometric measurements indicated an interaction of As2O3 with tubulin SH groups, without modification of the stoichiometry of paclitaxel binding to tubulin. Moreover, 4 .mu.M As2O3 inhibited the release of cytochrome c from isolated mitochondria by 78.+-.10%. Our results show that As2O3 and paclitaxel act antagonistically on mitochondria and microtubules and illustrate the need for careful evaluation of drug combinations.

AB In 1970, occupational agents were evaluated for the risk of brain-nervous system cancer in a cohort of 413,877 Finnish women with blue-collar occupations. Obsd. and expected nos. of incident cases and the intensity of exposure to 25 agents were generated for 183 job titles from 1971 to 1995. Poisson regression models linked incidence and exposure data. Increased risks were found for medium/high intensity of Fe (standardized incidence ratio [SIR], 2.15; 95% confidence interval [CI], 0.96-4.80), oil mist (1.95; 0.97-3.90), any Cr compds. (1.51; 0.85-2.67), electromagnetic fields (1.37; 0.98-2.10), aliph. and alicyclic hydrocarbons (1.34; 0.80-2.27), Pb (1.27; 0.81-2:01), Cd (1.26; 0.72-2.22), and arom. hydrocarbon compds. (1.20; 0.71-2.03). Study strengths included fair no. of cases, virtually complete case coverage, and a high-quality job exposure matrix. Ecol. design and cross-sectional job assessment introduced exposure misclassification and tended to drive risk ests. toward unity.

AB BACKGROUND: Occupational exposures may be related to the development of brain cancer. The objective was to estimate occupational-specific risk of gliomas and meningiomas among Swedish men and women gainfully employed in 1970 over the period 1971-1989, and the influence of occupational exposure to chemical substances. METHODS: A dataset linking cancer diagnoses from the Swedish national cancer register to occupational and demographical data obtained in the 1970 census was used to fit log-linear Poisson models, in order to obtain relative risks adjusted by age, period, geographical area and town size. Exposure to 13 chemicals was assessed using a Swedish job-exposure matrix. RESULTS: The main findings of this study among men were the increased risk of glioma with occupational exposure to **arsenic**, mercury, and petroleum products and of **meningioma** with lead. Women in occupational sectors with a higher socio-economic status showed an increased incidence of both, gliomas and meningiomas. CONCLUSIONS: Occupational exposure to some chemicals appeared to be related with an increased risk of glioma and meningioma in men. Exposures involved in glioma and meningioma development seemed to be different.

AB Recent clin. studies have demonstrated that As2O3 is an effective drug in the treatment of acute promyelocytic leukemia (APL) by inducing apoptosis and inhibiting the proliferation of leukemia cells both in vitro and in vivo. As a novel anticancer agent for the treatment of solid cancer,

As2O3 is promising, but no exptl. investigations of its efficacy on glioblastoma have been conducted at concns. that may be achieved clin. In addn., the cell proliferation and cell cycle regulating mechanism of As2O3 has not yet to be clarified, esp. in solid cancers. We investigated the effect of As2O3 on proliferation and cell cycle regulation with change in cyclins in two human glioblastoma cell lines differing in p53 status (U87MG-wt; T98G-mutated). Sensitivity to As2O3 varied depending on the dose with the IC50 of the U87MG and T98G cells being 1.78 and 3.55 .mu.M, resp. Anal. by laser scanning cytometry (LSC) indicated that As2O3 inhibited the proliferation of the two cell lines via cell cycle arrest both at the G1 and G2 phases. To address the mechanism of the antiproliferative effect of As2O3, we examd. its effect on cell cycle-related proteins by means of LSC, confocal microscopy and Western blot anal. As2O3 induced an increase in p53 level and a decrease in level of cyclin B1 combined with cell arrest at G2/M in both cell lines. Cell arrest in G1, however, was assocd. with a decline in cyclin D1 expression only in the wt U87MG cells. As2O3 also induced apoptosis of U87MG cells as evidenced by the presence of cells with fractional DNA content ("sub-G1" cell populations). The present evidence that As2O3 at relatively low concn. effectively inhibited proliferation of U87MG and T98G cells in vitro, suggests that the drug may be considered for in vivo testing on animal models and possibly clin. trials on glioma patients.

AB The use of several silver halide and chalcogenide IR transmitting fibers in the detection of cancer is investigated. As a test sample for all types of fibers we used a thin section of an entire rat brain with glioblastoma. Moving the sample with an XY stage maps across the whole tissue section with more than 200 spectra were recorded. Data evaluation was performed using Principal Components Anal. (PCA). The silver halide fibers have provided excellent results. The tumor was clearly differentiable from the normal tissue. It was not possible to identify the tumor region using chalcogenide fibers because the fiber has a very low transmittance in the important fingerprint region.

AB The aims of the present study were to assess the effects of **arsenic** trioxide on the nuclear matrix protein profiles of mouse **neuroblastoma** cells. Arsenic trioxide induces apoptosis of acute promyelocytic leukemia cells. Our results demonstrated that 2.mu.M As2O3 could significantly inhibit the growth of Neuro-2a cells. As early as 24 h after As2O3 treatment, we began to observe the alteration of nuclear matrix proteins and apoptosis in tumor cells by TUNEL assay but not by DNA ladder. An increase expression of Hsc in nuclear matrix proteins of 2.mu.M As2O3 treated cells was also noted. Our results also showed that before a mass range of apoptosis occurred, the compn. of nuclear matrix proteins had altered. Hence the alteration of nuclear matrix proteins, such as increased expression of Hsc, may be a sensitive indicator for the detection of early apoptosis.

AB In this paper the use of arsenic compounds as anticancer agents in clinical trials and in in vitro investigations is reviewed, including the experience at our institute. Treatment of newly diagnosed and relapsed patients with acute promyelocytic leukemia (APL) with arsenic trioxide (As2O3) has been found to result in complete remission (CR) rates of 85-93% when given by intravenous infusion for 2-3 h at a dose of 10 mg/day diluted in 5% glucose saline solution. Patients exhibit a response in 28-42 days. CR rates after administration of Composite Indigo Naturalis tablets containing arsenic sulfide and of pure tetraarsenic tetrasulfide reached 98% and 84.9%, respectively. At higher concentrations (1-2 microM), **arsenic** induced apoptosis, while at lower concentrations (0.1-0.5 microM), it triggered cell differentiation in vitro. As2O3-induced apoptosis has been observed in many cancer cell lines, including esophageal carcinoma, gastric cancer, **neuroblastoma**, lymphoid malignancies, and multiple myeloma. Its effectiveness was confirmed in the treatment of multiple myeloma. **Arsenic** compounds are effective agents in the treatment of APL and their activity against other types of cancer requires further investigation.

AB **Arsenic**, Cd, and Pb have been assocd. with various forms of **cancer**, nephrotoxicity, **central nervous system** effects, and cardiovascular disease in humans. Drinking water is a well-recognized pathway of exposure to these metals. To improve understanding of the temporal dimension of exposure to As, Cd, and Pb in drinking water, we obtained 381 samples of tap and(or) tap/filtered water and self-reported rates of drinking water consumption from 73 members of a stratified random sample in Maryland. Data were collected at approx. 2-mo intervals from Sept., 1995, through Sept., 1996. Concns. of As (range <0.2 to 13.8 .mu.g/L) and Pb (<0.1 to 13.4 .mu.g/L) were within the ranges reported for the USA, as were the rates of drinking water consumption (median <0.1 to 4.1 L/day). Cd was present at a detectable level in only 8.1% of the water samples. Mean log-transformed concns. and exposures for As and Pb varied significantly among sampling cycles and among respondents, as did rates of drinking water consumption, according to a generalized linear model that accounted for potential correlation among repeated measures from the same respondent. We used the intraclass correlation coeff. of reliability to attribute the total variance obsd. for each exposure metric to between-person and within-person variability. Between-person variability was estd. to account for 67, 81, and 55% of the total variance in drinking water consumption, As exposure (.mu.g/day), and Pb exposure (.mu.g/day), resp. We discuss these results with respect to their implications for future exposure assessment research, quant. risk assessment, and environmental epidemiol.

AB Background: Lead is only weakly mutagenic, but in vitro it inhibits DNA repair and acts synergistically with other mutagens. Lead acetate administered orally, cutaneously, or intraperitoneally causes kidney cancer, brain cancer (gliomas), and lung cancer in rodents, and acts synergistically with other carcinogens. Most cytogenetic studies of exposed workers have shown increases in chromosome aberrations or sister chromatid exchange, including some studies with positive-exposure response trends. There are eight studies of cancer mortality or incidence among highly exposed workers; most are cohort studies of lead smelter or battery workers exposed decades ago. Methods: We reviewed the epidemologic studies with regard to cancer. Results: These studies provide some evidence of increased risk of lung cancer (RR = 1.30, 1.15-1.46, 675 observed deaths) and stomach cancer (combined RR = 1.34, 1.14-1.57, 181 observed). However, the lung cancer findings are not consistent across studies, and confounding by **arsenic** may affect the study with the highest lung cancer RR. Exclusion of that study yields a combined lung cancer RR of 1.14 (1.04-1.73). There is little evidence of increased risk of kidney cancer (combined RR = 1.01, 0.72-1.42, 40 observed) or **brain cancer** (combined RR = 1.06, 0.81-1.40, 69 observed). However, two studies show a two-fold increase in kidney cancer, and one study shows a significant excess of gliomas. IARC classified lead as a 'possible human carcinogen' based on sufficient animal data and insufficient human data in 1987. Six of the eight studies cited above have been published since 1987. Conclusion: Overall, there is only weak evidence associating lead with cancer; the most likely candidates are lung cancer, stomach cancer, and gliomas.
AB . . . (combined RR = 1.34, 1.14-1.57, 181 observed). AB Recent clin. studies have shown that inorg. arsenic trioxide (As2O3) at low concns. induces complete remission with minimal toxicity in patients with refractory acute promyelocytic leukemia (APL). Preclin. studies suggest that As2O3 induces apoptosis and possibly differentiation in APL cells. Like APL cells, neuroblastoma (NB) cells are thought to be arrested at an early stage of differentiation, and cells of highly malignant tumors fail to undergo spontaneous maturation. Both APL and NB cells can respond with differentiation to retinoic acid (RA) treatment in vitro and probably also in vivo. For that reason we investigated the effect of As2O3 alone and in combination with RA on NB cell lines. In vitro, the no. of viable NB cells was reduced at As2O3 concns. around 1 .mu.M after 72 h exposure. The IC50 in six different cell lines treated for 3 days was in the 1.5 to 5 .mu.M concn. interval, the most sensitive being SK-N-BE(2) cells derived from a chemotherapy resistant tumor. The combined treatment with RA (1 and 3 .mu.M) showed no consistent addnl. effect with regard to induced cell death. The effect of As2O3 on NB cell no. involved As2O3-induced apoptotic pathways (decreased expression of Bcl-2 and stimulation of caspase-3 activity) with no clear evidence of induced differentiation. The in vivo effect of As2O3 on NB growth was also investigated in nude mice bearing tumors of xenografted NB cells. Although tumor growth was reduced by As2O3 treatment, complete remission was not achieved at the concns. tested. We suggest that As2O3, in combination with existing treatment modalities, might be a treatment approach for high risk NB patients. (c) 2000 Academic Press.

AB Controlled delivery of chemotherapeutic agents by biodegradable polymers is a new strategy that has been added to the **arsenal** available for the treatment of malignant neoplasms. This approach is particularly suitable for the management of **brain tumours** because of the constraints imposed by the blood brain barrier (BBB). The use of polymers for local drug delivery minimises systemic toxicity, while achieving prolonged elevation of intratumoural drug concentrations that results in improved efficacy. In addition, this strategy broadens the spectrum of drugs available for the treatment of neoplasms in the central nervous system to include agents whose efficacy is significantly limited by systemic toxicity or inability to penetrate the BBB. In this review, we discuss the rationale and background for the use of this novel approach. We also summarise the clinical trials and laboratory investigations leading to the development of local delivery of anti-neoplastic agents from biodegradable polymers for the treatment of malignant gliomas.

AB **Arsenic** trioxide-induced apoptosis was identified by morphol. change and nucleosomal DNA fragmentation in hematopoietic malignant cells and **neuroblastoma** cells. Arsenic trioxide directly induced apoptosis in the acute promyelocytic cell line NB4 cells at a low dose of 1 .mu.M, whereas all-trans-retinoic acid caused the cells to differentiate and finally induced apoptosis. In addn. to the involvement of caspase 3

in arsenic trioxide-induced apoptosis of NB4 cells, the activation of caspase 8 was also shown to be involved by Western blot anal. or by apoptosis inhibition assay using caspase 8 inhibitor Ac-IETD-CHO. The down-regulation of Bcl-2 protein was shown in arsenic trioxide-treated pre-apoptotic and early apoptotic mouse B-cell line LyH7 cells, which overexpress Bcl-2 protein, by the studies of Western blot and immunoelectron microscopy. **Arsenic** trioxide also induced apoptosis in the majority of **neuroblastomas**, cell lines. The **arsenic**-induced apoptosis in **neuroblastoma** cell lines was mediated by the activation of caspase 3 in all cases tested. In regard to the intracellular content of reduced glutathione in various **neuroblastoma** cell lines, the level in the cells sensitive to **arsenic** trioxide was under 40 nmol/mg protein, but the cells having more than 40 nmol/mg protein did not undergo apoptosis. N-acetylcysteine protected **neuroblastoma** cells from **arsenic**-induced apoptosis. Therefore, the intracellular glutathione content may be a good indicator of application of arsenic trioxide for various kinds of cancer cells. Our results raise the possibility that **arsenic** trioxide will be effective even against a solid tumor such as **neuroblastoma** and warrants clin. trials for patients with other kinds of tumors not only by systemic therapy but also using local therapy.

AB We have recently shown a close correlation between expression of the Multidrug Resistance-assocd. Protein (MRP) gene and the MYCN oncogene and provided evidence that high MRP expression is a powerful independent predictor of poor outcome in neuroblastoma (Norris et al., New Engl. J. Med., 334, 231-238, 1996). The effect of MYCN down-regulation on MRP expression and response to cytotoxic drugs was investigated in NBL-S neuroblastoma cells transfected with MYCN antisense RNA constructs. Concomitant with MYCN down-regulation, the level of MRP expression was decreased in the NBAS-4 and NBAS-5 antisense transfectants. These cells demonstrated significantly increased sensitivity to the high affinity MRP substrates vincristine, doxorubicin, sodium arsenate and potassium antimony tartrate, but not to the poor MRP substrates, taxol or cisplatin. Similarly, transfection of full-length MYCN cDNA into SH-EP neuroblastoma cells resulted in increased MRP expression and significantly increased resistance specifically to MRP substrates. The results provide evidence for the MYCN oncogene influencing cytotoxic drug response via regulation of MRP gene expression. Our data also provide a link between the malignant and chemoresistant phenotypes of this childhood malignancy.

AB Arsenic trioxide (As203) induces clin. remission in acute promyelocytic leukemia, even in all-trans retinoic acid-refractory cases, with minimal toxicity at low (1-2 .mu.M) concn. We exposed various neuroblastoma cell lines to As2O3 at a concn. of 2 .mu.M: as a result, seven of 10 neuroblastoma cell lines underwent apoptosis characterized by morphol. changes and nucleosomal DNA fragmentation. As2O3-induced apoptosis in neuroblastoma cells was shown to occur through the activation of caspase 3, as judged from Western blot anal. and apoptosis inhibition assay. It seemed that the sensitivity of neuroblastoma cells to As2O3 was inversely proportional to their intracellular level of reduced glutathione. Taken together these results indicate that As2O3 would be a candidate as a therapeutic agent for treatment of neuroblastoma, which is a solid tumor, not only by systemic therapy but also by local therapy.

AB Background: Primary **brain tumors** are among the most deadly of all cancers, with a 1-year survival rate of 52%. Certain elements, such as nickel, cadmium, chromium, **arsenic**, and beryllium, are established carcinogens in other organs. Silicon and titanium are suspected carcinogens and other elements are known to promote or inhibit the rate of tumor growth. Knowledge about the carcinogenicity of these elements in the brain is limited. In this study, we investigated the potential role of these elements as risk factors for human brain tumors. Methods: In a case-control study, we assessed brain biopsies from 12 patients with various types of primary brain tumors and in tumor-free brain tissue from 6 autopsy cases. We used energy- dispersive X-ray analysis (EDX) to determine if there were significant differences in the concentration of the study elements in tumors and in control brains. Results: In a bivariate analysis, a statistically significant association was observed between the presence of brain tumors and the concentrations of silicon ($p = 0.01$), magnesium ($p = 0.01$), and calcium ($p = 0.03$). Zinc

was also associated with a borderline significance (p = 0.05). No association was observed for nickel (p = 0.74). Although the magnitude of the observed association was estimated using multiple logistic regression analyses, the relative risk estimates were imprecise because of insufficient sample size. Further research using a larger sample size is needed to elucidate the role of these elements in human brain carcinogenesis.

AB Soft tissue sarcoma (STS) accounts for approximately 1% of all cancers diagnosed annually in the United States. Population-based data from Connecticut covering the years 1935-1989 have shown an increasing incidence of STS in both genders, with a greater increase among men than women. The recent increase in acquired immune deficiency syndrome-related Kaposi's sarcoma does not explain the upward trend in STS, dating back decades. Etiologic heterogeneity is suggested by epidemiologic variations that have been observed by subsite and cell type. Among the environmental factors associated with STS are external radiation therapy, Thorotrast, **arsenical** pesticides and medications, phenoxyherbicides, dioxin, vinyl chloride, immunosuppressive drugs, alkylating agents, androgen-anabolic steroids, human immunodeficiency virus, and human herpes virus type 8. In addition, STS occurs excessively among persons with certain heritable states including **retinoblastoma**, Li-Fraumeni syndrome, Gardner's syndrome, Werner's syndrome, nevoid basal cell carcinoma syndrome, neurofibromatosis type I, and some immunodeficiency syndromes. These risk factors account for a minority of STS cases but provide leads for further epidemiologic and interdisciplinary studies into the genetic and environmental determinants of various forms of STS.
AB . . . have been observed by subsite and cell type. AB THE DEVELOPMENT OF more cost-effective light sources for photodynamic therapy of brain tumors would be of benefit for both research and clinical applications. In this study, the use of light-emitting diode arrays for photodynamic therapy of **brain tumors** with Photofrin porfimer sodium was investigated. An inflatable balloon device with a light-emitting diode (LED) tip was constructed. These LEDs are based on the new semiconductor aluminum gallium **arsenide**. They can emit broad-spectrum red light at high power levels with a peak wavelength of 677 nm and a bandwidth of 25 nm. The balloon was inflated with 0.1% intralipid, which served as a light-scattering medium. Measurements of light flux at several points showed a high degree of light dispersion. The spectral emission of this probe was then compared with the absorption spectrum of Photofrin. This analysis showed that the light absorbed by Photofrin with the use of the LED source was 27.5% of that absorbed with the use of the monochromatic 630-nm light. Thus, to achieve an energy light dose equivalent to that of a laser light source, the LED light output must be increased by a factor of 3.63. This need for additional energy is the difference between a 630- and 677-nm absorption of Photofrin. Using the LED probe and the laser balloon adapter, a comparison of brain stem toxicity in canines was conducted. LED and laser light showed the same signs of toxicity at equivalent light energy and Photofrin doses. The maximal tolerated dose of Photofrin was 1.6 mg/kg, using 100 J/cm2 of light energy administered by laser or LED. This study concludes that LEDs are a suitable light source for photodynamic therapy of brain tumors with Photofrin. In addition, LEDs have the potential to be highly efficient light sources for second-generation photosensitizers with absorption wavelengths closer to the LED peak emission.
AB . . . benefit for both research and clinical applications. AB The fundamental event underlying scrapie infection seems to be a conformational change in the prion protein. To investigate proteins that might feature in the conversion of the cellular priori protein (PrP(C)) into the scrapie isoform (PrP(Sc)), we examined mouse **neuroblastoma** N2a cells for the expression and cellular distribution of heat shock proteins (Hsps), some of which function as molecular chaperones. In scrapie-infected N2a (ScN2a) cells, Hsp72 and Hsp28 were not induced by heat shock, sodium **arsenite**, or an amino acid analog, in contrast to uninfected control N2a cells, while other inducible Hsps were increased by these treatments. Following heat shock of the N2a cells, constitutively expressed Hsp73 was translocated from the cytoplasm into the nucleus and nucleolus. In contrast, the distribution of Hsp73 in ScN2a cells was not altered by heat shock; the discrete cytoplasmic structures containing Hsp73 were largely resistant to detergent extraction. These alterations in the expression and subcellular translocation of specific Hsps in ScN2a cells may reflect the cellular response to the accumulation of PrP(Sc). Whether any of these Hsps feature in the conversion of PrP(C) into PrP(Sc) or the pathogenesis of prion diseases remains to be established.

AB The toxic effects of arsenic at different cellular levels were assessed using two inorg. chem. species: sodium arsenite and sodium arsenate, representing the trivalent and pentavalent states of arsenic, resp. Mouse neuroblastoma cell cultures (Neuro-2a) were exposed for 24 h, and cytotoxic effects evaluated were: cell proliferation by quantification of total protein content; cytoplasmic membrane integrity to cytosolic lactate dehydrogenase leakage; lysosomal hexosaminidase release; lactate dehydrogenase activity; mitochondrial succinate dehydrogenase activity; relative neutral red uptake by lysosomes; lysosomal hexosaminidase sphingolipid degrdn. activity; and acetylcholinesterase activity. As(III) was five times more toxic than As(V) to neuroblastoma cell proliferation, but the relative extent of other alterations differed. Special sensitivity was detected for lactate dehydrogenase inhibition. Hexosaminidase activity was also very susceptible, being inhibited at low concns. and stimulated at high concns. Less sensitive were the inhibition of cell proliferation, relative neutral red uptake, and acetylcholinesterase activity. As(III) was lysosomotropic, with secretion of hexosaminidase, but the release was decreased by As(V). Mitochondrial succinate dehydrogenase was inhibited by As(III) and stimulated by As(V). Minor sensitivity to cytoplasmic lactate dehydrogenase leakage for both compds. also shows that functional metabolic alterations produced by arsenic are more important than structural damage.

AB Previous in vitro work demonstrated the incorporation of the major inducible 70k heat shock protein (i.e., 72k HSP) into the biologically active light nucleocapsid (L-NC) variant of canine distemper virus (CDV). Here, in vitro induction of the cellular stress response, characterized by elevated cytoplasmic and intranuclear 72k HSP, enhanced L-NC expression in mink lung cells supporting stable persistent infection by raccoon-origin CDV. Increases in L-NC were correlated to increased viral RNA production in cell-free transcriptional assays. The enhanced production of viral

transcripts with infected cells following stress response induction was confirmed by slot blot and Northern blot analysis of total cellular RNA and was reflected in increased total viral protein production. Post-shock increases in viral fusion (F) gene transcripts and F protein were associated with dramatic increases in viral cytopathic effect. Modest induction of cell-free infectious viral progeny was also documented. A similar effect of the cellular stress response upon viral protein expression, cytopathic effect, and cell-free infectious progeny release was demonstrated in murine **neuroblastoma** cells persistently infected with a canine CDV isolate. Alterations of the persistent viral phenotype were independent of the specific mechanism of stress-response induction (i.e., heat or sodium **arsenite**), supporting the role of the stress response and not a particular stressor in mediating these changes. These results document the ability of the cellular environment to alter persistent viral RNA metabolism, thereby altering the infection phenotype.

AB Induction of heat-shock proteins and glucose-regulated proteins in 9L rat **brain tumor** cells can be differentially elicited by sodium **arsenite**, cadmium chloride, zinc chloride, copper sulfate, sodium fluoride, and L-azetidine-2-carboxylic acid. The kinds of stress protein induced by the above chems. varied considerably, mainly detd. by the nature and the concn. of the chems., as well as the treatment protocols. In addn., at the concns. where stress proteins can be induced, the above chems. were able to suppress general protein synthesis and were cytotoxic. Enhanced phosphorylation of a protein with an apparent mol. wt. of 65 kDa was detected during the induction of stress proteins except in azetidine treatments during which uptake of phosphate by the cells was impaired after prolonged incubation. The phosphate moiety on the 65 kDa phosphoprotein appeared to be alk.-stable and two-dimensional gel electrophoresis revealed that the phosphoprotein resolved into four isoforms with isoelec. points ranging from 5.1 to 5.6. Enhanced phosphorylation of the same protein was also detected in heat-shocked and with angulatin A-treated 9L cells in which stress proteins were induced. It is suggested that this phosphoprotein may be a common target for heat stress response-stimulated phosphorylation and important in the further metabolic responses of the cell to stress.

AB Serum arsenic concentrations of persons suffering from renal failure and undergoing hemodialysis treatment (n = 85) and of healthy controls (n = 25) were determined by hydride-generation AAS technique after microwave digestion. The results were evaluated by comparing the values of both groups, considering physiological factors and individual data, as well as comorbid conditions of the hemodialysis (HD) patients. Serum arsenic levels were diminished in the patient group compared with controls (mean values 8.5 +/- 1.8 ng/mL vs 10.6 +/- 1.3 ng/mL). Furthermore, additional diseases within the hemodialysis group, particularly injuries of the **central nervous system** (**CNS**), vascular diseases, and **cancer**, were correlated to occasionally markedly decreased serum **arsenic** concentrations. It was concluded that arsenic homeostasis is disturbed by HD treatment and certain additional diseases. Desirable arsenic concentrations in the body seem to be reasonable. This consideration results in the conclusion that arsenic could play an essential role in human health. Thus, reference arsenic concentrations in different human tissues and body fluids should be established in order to recognize not only arsenic intoxication, but also arsenic deficiency. Perhaps arsenic deficiency contributes to the increased death risk of HD patients, and therefore, arsenic supplementations for patients with extremely low serum arsenic concentrations should be taken into account.

AB PCR and Southern blot analyses demonstrate that mRNA for heme oxygenase (HO), a well known 'stress protein' in a number of tissues, is present in human retina. Western and northern blots show that the protein and mRNA are also expressed in human Y-79 **retinoblastoma** cells in culture and that the HO enzyme is rapidly induced by its substrate, heme. Moreover, HO is also induced by two chemicals, sodium **arsenite** and menadione, that act as agents of oxidative stress. HO is the regulatory enzyme in the heme degradative pathway and an increase in its activity could lead to the accumulation of bilirubin, an antioxidant, in the cell at the expense of heme, a prooxidant. The HO pathway may thus be of importance in protecting the retina against oxidative stress in vivo. Moreover, the Y-79 culture system should provide an excellent model for use in examining stress mechanisms in retinal cells at a molecular level.

AB The authors review the available evidence on cancer risk associated with exposure to agricultural chemicals. Agricultural workers generally show a lower cancer mortality compared with other occupational categories. This observation is currently believed to be due to lower cigarette consumption. However, for some types of tumours (lymphoma, leukaemia, myeloma, soft tissue sarcoma, skin, prostate, **brain** and stomach **tumours**), mortality is higher among agricultural workers. The only chemical substances used in agriculture for which the IARC Monographs have established the existence of sufficient evidence of carcinogenicity for man are **arsenical** compounds and mineral oils; for other substances there is clear evidence of carcinogenicity in experimental animals, mostly in the absence of human data. In the case of exposure to phenoxyacetic herbicides, the available epidemiological evidence is contradictory, with excesses of non-Hodgkin lymphoma and soft tissue sarcoma reported in some studies but not in others. Cohort studies have been performed among insecticide production workers and spray operators (with excesses of lung tumour), and among grain processing workers (with excesses of non-Hodgkin lymphoma in particular). A number of case-control studies are also available, especially concerning tumours of the lymphatic and haemopoietic systems and ovarian tumours.

AB In an effort to better understand the epidemiology of cancer in Zaire, a retrospective review of biopsy-proven malignant tumors was undertaken. Of 188 biopsies taken from children aged 0-15 years over a 4.5 year period, 73 (39%) revealed malignancy. Fifty-six percent of patients with malignant tumors were boys. Lymphoma was the most common tumor (28 patients, 15 with Burkitt's lymphoma). Sarcoma (15 patients), carcinoma (8 patients), Wilms' tumor (6 patients), and retinoblastoma (5 patients) were also seen. Lymphomas were most heavily represented in the first 5 years of life, while sarcoma and carcinoma accounted for most of the malignancies in children after 10 years of age. Lymphomas and sarcomas are relatively more common in Zaire than in North America and Europe, while leukemia and **central nervous system tumors** are

notably less common in Zaire. In view of current limitations on health care in rural Zaire, cancer care should be directed toward early diagnosis, quick referral for appropriate surgical care, and use of the limited **arsenal** of chemotherapy.

AB A conditioning treatment of 30 min at 42.degree.C or 43.degree.C, followed by a 4-h recovery period at 37.degree.C, induces thermotolerance state in the cytoskeleton of Reuber H35 hepatoma cells and N2A neuroblastoma cells.

Evidence for the involvement of heat shock proteins in the development of thermotolerance in the cytoskeleton has been obtained from the following observations: (a) only those conditioning treatments inducing the enhanced synthesis of heat shock proteins (HSPs) are able to induce the heat-resistant state of the cytoskeleton; (b) prevention of HSP synthesis by actinomycin D or cycloheximide also prevents the acquisition of thermotolerance in the cytoskeleton; (c) an alternative inducer of HSP synthesis, sodium **arsenite**, is also able to induce the cytoskeletal thermotolerance; (d) the kinetics of development and disappearance of thermotolerance in the cytoskeleton is parallel to the kinetics of accumulation and decay of HSPs. The possible function of HSPs in the heat-resistant cytoskeleton of H35 hepatoma and N2A **neuroblastoma** cells is discussed.

AB The cytoskeleton of **neuroblastoma** cells, clone Neuro 2A, is altered by 2 stress conditions: heat shock and **arsenite** treatment. Microtubules are reorganized, intermediate filaments are aggregated around the nucleus, and the no. of stress fibers is reduced. Since both stress modalities induce similar cytoskeletal alterations, no thermic denaturation of .gtoreq.1 cytoskeletal components can be involved in this process. Heat-shock proteins (hsps) are induced both by heat and by arsenite. However, cells treated with arsenite synthesize hsp28 which is not detected in heat-treated cells. Synthesize of all hsps is prevented by addn. of actinomycin D or cycloheximide. Under these conditions no alterations are obsd. in the organization of microtubules and intermediate filaments during heat or arsenite treatment. However, these drugs are not able to prevent the rapid loss of stress fibers. A reformation of the cytoskeleton during the recovery period proceeds within 3 h and is also found to occur in the presence of a protein synthesis inhibitor. Apparently, reorganization of microtubules and intermediate filaments during a stress treatment requires the synthesis of a new protein(s), probably hsp(s).

AB Voltage-gated changes in cytosolic free calcium ion concentration were measured in single, differentiated cells of mouse **neuroblastoma** clone N1E-115 using the calcium-sensitive dye **arsenazo** III (AIII). In cells bathed in normal medium containing 10 mM calcium, the changes in AIII absorbance during a single action potential indicated an increase of 1.4 nM in cytosolic calcium. When 10 mM tetraethylammonium (TEA) was added to the bath, the action potential became prolonged and the change in cytosolic calcium increased to 3.9 nM. Under these conditions, repetitive stimulation at 0.5 Hz or faster caused a gradual decline in the amplitude and duration of the action potential and a gradual decline of the change in cytosolic calcium associated with each action potential. The amplitude of the prolonged after-hyperpolarization (AHP) that follows the action potential was found to reflect the magnitude of the change in

cytosolic calcium. An action potential elicited in the cell soma caused an increase in cytosolic calcium in the soma, neurite, and growth cone regions of a single cell, indicating that the membrane of all three regions possesses voltage-gated calcium channels. Estimation of calcium flux per unit area of membrane suggests a distinct topographical organization of calcium channels. Calcium channel densities in the growth cone and cell soma regions are similar and significantly higher than that in the neurite.

AB NIE-115 mouse **neuroblastoma** cells were injected with the Ca indicator dye **arsenazo** III. Optical absorbance changes during voltage-clamp depolarization were used to examine the properties of the 2 Ca currents present in these cells. The rapidly inactivating Ca current inactivates by a voltage-dependent intracellular Ca during depolarization to >-20 mV. Lowering the extracellular Ca concn. affects the 2 Ca currents unequally, with the slowly inactivating current being reduced the most. Intracellular Ca falls very slowly after a depolarization. The rapidly inactivating Ca current is responsible for a Ca action potential under physiol. conditions. In contrast, it is unlikely that the slowly inactivating Ca current has an important elec. role. Rather, its function may be to add a further increment of Ca influx over and above the Ca influx through the rapidly inactivating Ca channels.

AB Recent progress in brain tumor biology research has helped us to understand the causes of our failure to improve patient survival with current therapeutic approaches. Present combination regimens of surgery, radiotherapy, and chemotherapy fail to address adequately two inherent biologic properties of brain tumors: tumor-induced host immunosuppression and tumor cell heterogeneity. Future success in immunotherapy will depend on our ability to dissect the mechanisms involved in tumor-host interactions. Also, therapies may have to be individualized. The potential for MAs in research and clinical application is great owing to their unlimited discriminative power for molecular and functional characterization. Differential diagnosis of difficult cases, such as parenchymatous tumors or neoplastic cells in CSF, with panels of MAs will be available in the near future. The use of MAs to direct localization and therapy of brain tumors is also promising, as evidenced by the preliminary data from our laboratory and from those of other workers. Other applications of MAs, such as prevention of invasion and metastasis by targeting cell surface molecules involved in cell-matrix attachment function, are also under study. Future refinement in MA-specificity and in enhancement of MA-delivery to tumor sites will significantly complement new therapeutic approaches. As brain tumors evade immunosurveillance through active participation in inducing tumor-specific immunosuppression, successful immunotherapy, either passive serotherapy or active immunization, will be best achieved in patients with a slight or moderate immunosuppressive state. Alteration of immune status with various biologic response modifiers to boost host reactivity against tumors will be an important adjunct in our **arsenal** against **brain tumors**. IFNs, with their direct tumoricidal activity, and lymphokines (such as interleukin-2) may be such reagents with a promising future.

AB Hyperthermia of mammalian cells results in a repression of normal protein

synthesis activity concomitant with an accumulation of a small number of heat shock proteins, the stress proteins (SPs). This repression is believed to be controlled at levels both of transcription and translation. Neither the mechanism of induction nor the function of the SPs is known. The induction of SPs in two mammalian cell types after hyperthermia (43 C, 30 min) and sodium-**arsenite** treatment (50 uM) is reported in this paper. The apparent mol wts of the SPs of Reuber H35 hepatoma cells and **neuroblastoma** N2 cells were 28, 65, 70, 84, 100 kD and 68, 70, 84, 100 kD, respectively. Hyperthermia caused the breakdown of microfilaments in the H35 cells, whereas the microtubules and intermediate filaments (vimentin and keratin 18) remained intact. In the neuroblastoma N2 cells, the microfilaments remained intact, while the microtubules became disorganized. The vimentin was capped around the nucleus as a consequence of the microtubule disruption. It was concluded that no particular stress-induced alteration in the cytoskeleton is needed for induction of stress protein synthesis. (5 Refs)

AB To investigate the associations of water characteristics in sewage with 23 SMSAs mortality rates from cancers and cardiovascular diseases in 1970, data from samples of sewage obtained in 1979 and 1980 were examined. Both metallic and organic characteristics of the sewage were used. Whenever a significant simple correlation was found between a component of sewage and mortality, the corresponding partial correlation was computed after holding population and socioeconomic factors as covariates constant. The significant positive associations found include cobalt and esophageal cancer for both sexes; chromium and cancers of liver, bile ducts, and gallbladder, cobalt and leukemia, trichloromethane or total volatile organics and **cancers** of **brain** and other parts of nervous system, and trichloromethane and leukemia for males; manganese and cancers of buccal cavity and pharynx, total organic ranks and esophageal cancer, copper and **arsenic** and rectum cancer, total inorganic ranks or cobalt or pesticides and pancreas cancer, copper and cancers of other unspecified urinary organs for females. Some significant negative associations were also found. As anticipated, the mortality from ischemic heart disease was negatively associated with the hardness or hardness components. Such an association was also found with deaths from prostate cancer and leukemia for males and with total cancer death rates for both sexes. Interpretations for the hardness associations were discussed. Some covariates such as percent manufacturing industry, percent nonwhite population, and smoking could be important factors contributing to the hardness associations. However, the finding of the negative association between ischemic heart disease and hardness, for which there is much other evidence suggests that the method of using the sewage variable to examine environmental relationships to mortality has a degree of validity. The

unexplained but apparently not artifactual relationship between various metals and specific cancer rates need further study.

AB Responses (62) to a questionnaire sent to former university students and others who in 1943 consumed sausage meat containing arsenic (0.59 or 1.36 g arsenious oxide/kg meat) revealed three persons with rodent ulcers (basal cell carcinoma). In one patient, arsenic levels in excised skin lesions declined from 0.19 ug/g in 1965 to 0.002 ug/g in 1978. All three patients with ulcers had at least 3 yr exposure to tropical sun before any ulcer appeared, but whether retained **arsenic** had increased the patients' susceptibility to UV irradiation or whether irradiation alone had been responsible could not be determined. Among 12 subjects known to have died, two died of **neoplasms**: one with a **brain tumor** (at age 55), and one with cancer of the pharynx (at age 28). The remainder died of other causes or cause could not be obtained. (5 Refs)

AB This paper intends to analyse two cases of speech arrest. The patients suffer from a frontal tumor which affects the supplementary motor area; one case was accompanied by 'pure' agraphia. Case 1, a 32 year-old right-handed male, had speech arrest and 'pure' agraphia. Spontaneous speech, naming, repetition and reading are not impaired. Radiographic (CAG CT scan) and surgical localization checks were done on the paramedian left frontal lobe (which controls supplementary motor area) and a solid tumor nodule about 1.5 by 2 cm in size was detected at the base of the left second frontal convolution (F2). Writing disturbances continued until one and a half months before the tumor was removed. He cannot write his signature, do spontaneous writing, take dictation or do copying. After the

partial excision of the solid tumor nodule at the base of left F2, both speech arrest and writing disturbances were improved. Neither apraxia nor agnosia were noticed. Case 2, a 26 year-old right-handed male, had speech arrest only. Speech and writing functions were not impaired. He is intellectual. An **oligodendroglioma** was found in the left frontal lobe which affected the supplementary motor area but the lesion was not extended into the left second frontal convolution. In both cases, speech arrest was of the 'total' type according to **Arseni**'s subdivision, and verbal repetition did not appear. We realize that the lesion in the supplementary motor area causes speech arrest and that the left F2 causes 'pure' agraphia. We compare our result with similar cases in the literature, especially with 'pure' agraphia cases caused by a lesion in Exner's writing center. We conclude that 'pure' agraphia can be classified under the category of autonomic-kinesthetic disorders in writing functions caused by frontal lobe lesion.

AB . . .. a 26 year-old right-handed male, had speech arrest only. Speech and writing functions were not impaired. He is intellectual. AB Although polyvinyl chloride has been produced from vinyl chloride monomer for more than 40 years, recognition of toxicity among vinyl chloride polymerization workers is more recent. In the mid 1960s, workers involved in cleaning polymerization tanks were found to have acro osteolysis. In 1974, the same population of workers was found to be at risk for an unusual type of hepatic fibrosis and angiosarcoma of the liver. The authors describe two cases of vinyl chloride associated liver injury, one of hepatic fibrosis and one of angiosarcoma. Histologic features of these lesions are similar to the hepatic fibrosis and angiosarcomas resulting

from chronic exposure to inorganic **arsenicals**. Preliminary studies suggest that the toxicity of vinyl chloride may result from formation, during high dose exposure, of active metabolites by mixed function oxidases of the liver. Epidemiologic studies indicate an increased incidence not only of liver disease, but also of **cancers** of the **brain**, lung and possibly other organs.

AB Three hundred C3H mice were used to ascertain the validity of treatment of **brain cancer** with **arsenicals** and bacterial polysaccharide. It was found that this method of therapy was efficacious. Also, that a prophylactic effect was demonstrated. 2. In 14 patients with advanced intracranial neoplasm it was found: a) that no curative effect could be brought about once the cancer had spread beyond a certain point. This "point of no return" depends on tumor type, location and degree of brain destruction and general state of debility. b) That subjective and even some temporary objective improvement was possible even in advanced cancer. Necrosis of cancer tissue, that could be attributed to the therapy, was found in a number of cases. c) That some cases of **brain cancer** showed remarkable response to this form of therapy; more so if radiation therapy was given at the time of administration of the **arsenical** and bacterial polysaccharide. d) That some cases of brain metastasis showed "complete" destruction of the **neoplasms** in the **brain** although the patient subsequently died of the primary neoplasm and multiple metastasis. e) That the principle of enhancing the deposition of the curative material in the neoplasm by the use of bacterial polysaccharide is valid. f) That if this method of treatment (i.e. **arsenical**, bacterial polysaccharide and radiation) is instituted in the "early" cancer cases we may find it to be an efficacious mode of attack. g) That aresnical by mouth and bacterial polysaccharide by I.M. injection may be useful as a prophylactic to the formation of cancer. This may be contemplated for use in families that seem to show a predisposition to cancer formation. A mode of administration would probably be somewhat similary to the maintencance therapy described in the body of this paper. h) That bacterial polysaccharides have been shown to have the ability to destroy cancers.3,9 This method of enhancing the patients antigen-antibody reaction may eventually be used as a means of gaining an efficient vaccine in cancer therapy. i) Wherever possible definitive surgery should be carried out before the **arsenical**-bacterial polysaccharide-radiation method is instituted. j) In **brain cancer**, after craniotomy with removal of all or part of the neoplasm where feasible, the patient

should be left with a subtemporal decompression. This will allow for the oedema of the brain that occurs with cerebral radiation therapy. k) That the principle of destruction of the cancer by certain special substances is valid. That the increase of affinity between cancer and destructive (curative) material can be brought about by administering a bacterial polysaccharide at the same time and that radiation therapy may enhance the beneficial effects of this method. 1) That the principle of brining the greatest toxicity to the cancer cells and the least toxic effect to the organism has been applied in the use of this method of treatment. m) That in some cases the cancer may not be destroyed by this therapy but may be made to retrogress or be held in check.

AB Protein metabolism in mouse liver was studied using 131I-labeled albumin as a tracer and differential centrifugation for the isolation of protein fractions. The hydrolysis of 131I-labeled albumin in mouse liver cells and theuptake of 131I-albumin by brain tumor cells was studied in vitro. The influence of clearance from the blood stream on brain tumor uptake of 74As-labeled arsono-poly-L-lysine and 131I-labeled albumin was studied in mice.

AB The tumor concns. in C-57 mice of arsenate and tryparsamide (I) followed similar courses. Highest levels appeared immediately and 15 min. after injection. There was a sharp decline during the first 4 hrs. Arsenate values fell from 2.70 (% of injected dose/g. of tumor) at 15 min., to 0.65% in 4 hrs.; I dropped from 2.87 to 0.18% in the same period. The initial arsonopolylysine (II) values were lower than those of the above and rose to 2%. All compds. passed into the brain sparingly. Arsenate concns. were relatively high. The **tumor**-to-**brain** ratios of **arsenate** were 7:1 at 1-3 hrs.; I ratios were 33:1 at 1 hr. and 14:1 at 3 hrs.; and II ratios were 14:1 at 2 hrs. and 21:1 at 7 hrs. The tumor-to-muscle ratios of arsenate and I were .apprx.2:1. II was const. at 0.6-1.0% for 8 days. Blood-clearance patterns for arsenate and I indicated a rapid loss of org. material. II concn. in liver was 35% in 4 hrs.; in the kidney, it was .apprx.10% for 8 days.

AB Striking differences are reported in cancer incidence, situation and histopathological type between and within races of Africa. The hypothesis of the uniform liability of mankind to cancer is questioned by the fact that Negriform races (half-Hamites, Nilotic and W. African Negroes, pygmies and Bantu-speaking) generally have a much lower incidence than that seen in Western races (in which the data suggest that 80% or more of the cancers are environmentally-induced and potentially preventable) or in U.S nonwhites. Common to the Negriform races are primary cancer of the liver, Kaposi's sarcoma, Burkitt's tumor and (in some regions) esophageal cancer, while leukemia and cancers of the stomach, large intestine, breast, endometrium, ovary and brain are generally rare. Mixed races (colored) show high rates of stomach and liver cancer. Asians have a lower mortality, while South African whites resemble U.S whites, except for higher rates of lip, tongue, stomach, prostate, skin and bone cancer in the former group. The etiological aspects of various tumors are discussed with regard to lymphomas and cancer of the lip (sunlight and tobacco),

mouth, postnasal space, esophagus, liver (fungal toxins?), sinuses (snuff), lung (smoking, **arsenic**), mesothelium (asbestos), uterus, penis (circumcision, ablution), bladder (bilharziasis), prostate, skin (sunlight, tropical ulceration, other ulcers), eye, conjunctiva (sunlight) and **brain**. The influences of westernization on **cancer** incidence in African Negroes is also discussed.

AB Arsanilate-As74 was used as a tracer in tissue-uptake studies in order to obtain increased localization of the isotope in brain tumors of mice. In terms of arsanilate, the uptake of a label into tumor from azoprotein approached that of uncoupled material only with the use of extensively labeled protein. Large, persistent accumulations of arsonazoalbumin-As74 were found in liver and kidney even with as little as 1-2 moles arsanilate/mole protein. The uptake in kidney and the rate of disappearance of injected arsonazoalbumin-As74 from blood varied directly with the amt. of arsanilate bound to protein. The correlation between these factors was poor for liver and tumor and negative for muscle.
